Table 2 Particle Structure Mass (experimental) Mass (calculated) $4t^{\circ} + 5b$ $4t^{\circ} + 5b$ $5t^{\circ} + 30b$ $5t^{\circ} + 30b$ $5t^{\circ} + 16b$ $19t^{\circ} + 3b$ $19t^{\circ} + 3b$ $19t^{\circ} + 16b$ $36t^{\circ} + 12b$ $36t^{\circ} + 16b$ 105·429 105·429 139·570 139·570 134·982 493·989 493·989 498·250 938·050 $\begin{array}{c} 105 \cdot 659 \pm 0.002 \\ 105 \cdot 659 \pm 0.002 \\ 139 \cdot 577 \pm 0.014 \\ 139 \cdot 577 \pm 0.014 \end{array}$ 134-974 ± 0·014 134-974 ± 0·018 493-78 ± 0·17 493-78 ± 0·17 497-82 ± 0·25 938-256 ± 0·005 939-550 ± 0·005

From the series of simultaneous equations presented in Table 1, the best values for the bound rest-masses of the tamaid and bach are found to be $t^0 = 25.9477$ ± 0.009 MeV and $b=0.3277\pm 0.010$ MeV, respectively. The masses of the various subnuclear particles have been calculated using these figures and the results are given in the ultimate column of Table 2. The agreement shown with the experimental values suggests that the mass defect effect produced by adding unit tamaids to the structure of subnuclear particles must be remarkably constant.

I thank O. F. Newman for undertaking the statistical

Some Preparative Details of the Nd3+/SeOCl2 Laser

Heller and Lempicki^{1,2} have reported a liquid laser, using a solution of neodymium ions in selenium oxychloride and tin tetrachloride, which operates at room temperature. My investigations have shown that the successful operation of this system is critically dependent on the purity of the components and the method of preparation. The rapid quenching of Nd³⁺ fluorescence by impurities, containing low atomic weight elements, makes it necessary to purify carefully the solvents and exclude moisture during preparation. Impurities can also be detrimental to the optical quality of the solution. A method of preparation is described here which has been found to give a working solution. Some preliminary results using a simple cell are briefly reported.

All handling and distillations were carried out in a dry 'Teflon' sleeving was used on all nitrogen atmosphere. glass to glass joints. Selenium oxychloride (B.D.H.) was fractionally distilled at reduced pressure (60° C at 14 mm of mercury). Marked decomposition occurred if the distillation was done at or near atmospheric pressure. Tin tetrachloride (B.D.H.) was allowed to stand over mercury for 24 h before fractional distillation. The mixed solvent was made by adding selenium oxychloride to

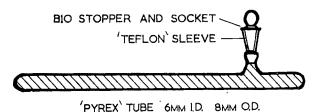

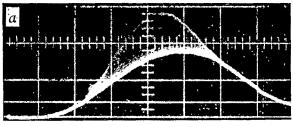

Fig. 1. 'Pyrex' cell with flame-sealed ends.

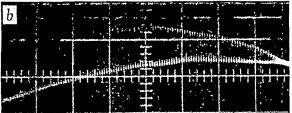

Fig. 2. a, Cell output at 600 Joule input energy, divisions = 75 μ sec; b, expanded portion of the spiking at the same energy input, divisions = 20μ sec. Detector rise-time approximately 0.5 μ sec.

11.5 ml. tin tetrachloride to give 50 ml. of solution. The prepared solvent was refluxed with neodymium oxide (Johnson, Matthey and Co. Ltd., 99.9 per cent) until complete solution occurred (2-3 min) and the solution was filtered through a ground-glass sinter. The rate of solution was dependent on the particle size of the oxide and further grinding may be necessary. The final solution had a pale reddish violet colour.

A 0.5 normal Nd3+ solution was tested in a simple cell, similar to that described recently by Lempicki and Samelson³ (Fig. 1). This cell was pumped in a 12.5 cm long elliptical cavity, and the output, through a filter centred at 10,500 Å, band pass 300 Å, is shown in Fig. 2. Feedback occurs through total internal reflexions within the tube, and the stimulated emission is not collimated. The regular nature of the spiking is shown on the expanded time base in Fig. 2b. No value has been obtained for the laser threshold in this cell because the minimum energy input with the available equipment is 300 joules. A high gain for the material was, however, indicated by decreasing the pumped length of the tube to 5 mm; at an input of 600 Joules distinct spiking was still observed.

Taylor Vortices with Eccentric **Rotating Cylinders**

THE stability of circumferential laminar flow between rotating concentric cylinders has been extensively investigated, the classical work being that of Taylor¹. The effect of eccentric positioning of the cylinders, however, has received relatively little attention, although this further complication is of technological interest in connexion with operating journal bearings at very high speed in the so-called superlaminar regime. I have carried out experiments with an eccentrically positioned rotor inside a stator, the axes being parallel, and I have already described how the Taylor vortex pattern still appears, but with the critical speed raised appreciably above Taylor's value for concentric cylinders.

The vortex pattern, made visible by suspending small aluminium particles in the test fluid, is substantially similar in appearance for both concentric and eccentric positioning of the cylinders, but the spacing diminishes at high eccentricity ratios (that is, displacement of centres divided by radial clearance) and the pattern then becomes confused because of reverse flow and vortex waviness.

In a recent communication², I described a simple and sensitive method for detecting the onset of Taylor vortices, using a small constant-temperature heated probe which traversed slowly and axially in the clearance space. The percentage increase in critical speed over the concentric value was almost the same at a given eccentricity ratio, for clearance ratios (that is, radial clearance divided by rotor radius) of 0.478 and 0.274 (ref. 2). I have now extended these measurements to six clearance ratios from 0.138 to 0.478, using oils and air as test fluids, and I have again found that the clearance ratio has little effect on the critical speed ratio.

These results, obtained using a heated probe, all showed critical speeds above those determined by visual observation, and it seemed desirable to check the determination by direct measurement of rotor torque, for this is the quantity of most practical significance. I have made torque measurements using a torsion-mounted motor for a clearance ratio of 0.207, and in Fig. 1 it can be seen that there is the expected increase of torque as centrifugal effects begin to modify the laminar flow regime. For concentric conditions the change of slope of the torque against speed graph is clearly marked, but, because the cylinders are made eccentric, the critical change becomes progressively less sharply defined, especially for eccentricity ratios over 0.5. The critical speed is clearly seen to increase with eccentricity ratio and, as shown in Fig. 2, the critical conditions determined by heated probe

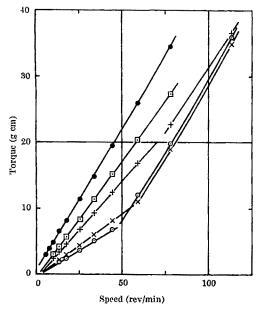

Fig. 1. Variation of torque with eccentricity ratio, ϵ . Rotor dimensions; 2-48 in. diameter, 14 in. long and 0-26 in. radial clearance; oil 10-5 cst. The various eccentricities, ϵ , are \bigcirc , 0; \times , 0-47; +, 0-59; \square , 0-71; \bullet , 0-83.

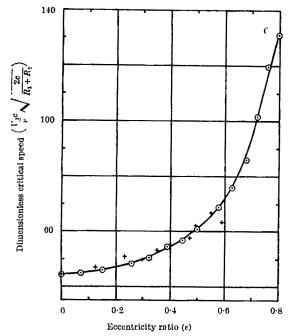

Fig. 2. Effect of eccentricity ratio on critical speed. The dimensionless critical speed is $\frac{V_1c}{\nu} \sqrt{\frac{2c}{R_1+R_1}}$ where V_1 is the surface velocity, ν is the kinematic viscosity, and R_1 and R_1 are the inner and outer radius, respectively. \odot , Is a heated probe indication, and + are torque measurements.

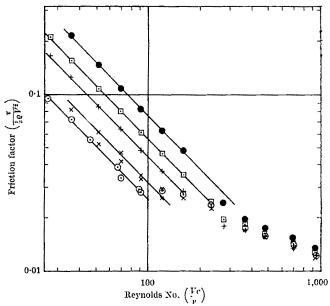

Fig. 3. Effect of eccentricity ratio on the friction factor. The friction factor is $\frac{\tau}{\frac{1}{2}QV^2}$ where τ is the shear stress at the rotor and g the density. The various eccentricities, ϵ , are: \bigcirc , 0; \times , 0.47; +, 0.59; \square , 0.71; \bigcirc , 0.88,

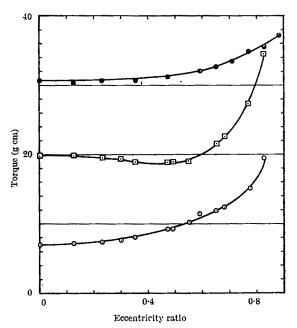

Fig. 4. Effect of eccentricity ratio on torque. •, 152 r.p.m., 3.5 cst; (superlaminar); •, 78 r.p.m., 10.5 cst (intermediate); •, 44 r.p.m., 10.5 cst (laminar).

traverse and by torque measurement are in adequate accord.

If the measured torques are expressed conventionally as the ratio of shear stress to dynamic pressure, the resultant friction factor against Reynolds number diagram is as shown in Fig. 3. There is some tendency for the critical condition to occur at a constant level of friction factor, and the superlaminar friction factors are less dependent on eccentricity ratio than the laminar friction factors. This last point is also brought out in Fig. 4, where the actual torque readings are seen to increase more rapidly with eccentricity ratio for a speed in the laminar range (and in agreement with calculations based on viscous flow theory) than for a speed in the superlaminar range. The intermediate curve shows the inter-

esting situation where an initially superlaminar flow at low eccentricity ratios becomes laminar at the same speed for higher eccentricity ratios with a consequent decrease in friction at intermediate eccentricity ratios.

These results show that the critical condition is difficult to determine accurately by measuring gross torque at other than small eccentricity ratios. I therefore investigated the use of a small constant-temperature heated probe mounted flush with the surface of the stator to detect the change in local heat transfer coefficient associated with the onset of Taylor vortices.

Under concentric conditions and at eccentricity ratios up to about 0·3, the rate of heat transfer was observed to change very rapidly at the critical condition, the direction of the change depending on the axial position of the probe relative to the vortex system. As the eccentricity ratio was progressively increased, the change became less definite, which indicated a change of flow regime, and consistent results could not be obtained.

I therefore regard the detection method using a traversing heated probe² as relatively the most satisfactory, but further studies at high eccentricity ratios are desirable.

CHEMISTRY

Structure of the NH Stretching Band and (NH).. N Hydrogen Bond Frequencies in Purine

THE AH stretching band of a strongly hydrogen bonded AH... B system is usually very broad and may present a complicated structure consisting of numerous sub-bands. In order to explain these sub-bands, the frequency modulation theory—that is, that the sub-band frequencies can be represented by the expression $v = vAH \pm nv(AH) ... B$, where $n = 0, 1, 2 \dots$ and $\nu(AH) \dots B$ is any hydrogen bond frequency—has been advanced in the literature 1-3. In the case of imidazole, which contains strong NH..N hydrogen bonds, we have suggested that the hydrogen bond-frequencies do not seem to be a decisive factor in determining the sub-band structure of the vNH absorption4. In this communication, we wish to show that the same is true for purine, which contains a similar hydrogen bonded system, by comparing the behaviour of the vNH sub-bands and the far infrared hydrogen bond frequencies of different isotopic species at different temperatures.

The crystal structure of purine has been determined⁵. The molecules are linked in infinite chains by short hydrogen bonds, the N. N distance being 2.85 Å. The unit cell contains four molecules, and the symmetry of the orthorhombic crystals belongs to the space group $Pna2_1$. There are twenty-one lattice vibrations which can be represented by $5A_1 + 6A_2 + 5B_1 + 5B_2$. Thus only fifteen lattice modes are infrared active.

In the observed spectrum of crystalline purine there are ten absorption bands in the 300–33 cm⁻¹ region (Fig. 1, Table 1). Two of them, at 268 and 230 cm⁻¹, correspond to the internal modes while the remaining bands are likely to be caused by the external vibrations, which necessarily include the hydrogen bond motions. No detailed assignment of the latter can be given at the present; however, the strongest band at 110 cm⁻¹ is believed to be caused by

2,557 2,538	2,562 2,540	2,580	2,575

a predominantly hydrogen bond stretching mode, by analogy with the imidazole crystal.

There is an important temperature effect on the lattice vibrations of purine. As shown in Table 1, the frequencies shift to higher wave numbers when the crystal is cooled to liquid nitrogen temperature. The isotopic effect—that is, when the CH group between the imidazolic nitrogens is deuterated (purine-8-d₁)—on the other hand, does not shift the lattice frequencies within the experimental error $(\pm 1 \text{ cm}^{-1})$.

In the 4,000–2,000 cm⁻¹ region of crystalline purine only the NH and CH stretching frequencies are expected. The vNH absorption band of purine (Fig. 2) has its centre of gravity near 2,700 cm⁻¹ and a half-width of about 600 cm⁻¹. There are ten relatively well defined and strong sub-bands which disappear in the spectrum of ND substituted purine (purine-7-d₁) and are thus caused by hydrogen bonded NH groups. Their frequencies are given in Table 2. The CH stretching fundamentals, between 3,100 and 3,000 cm⁻¹, are much narrower and can be easily distinguished from sub-bands by deuteration.

The temperature and isotope effects on the lattice frequencies and on the sub-maxima of the vNH band can be compared in order to check the relationship required by the frequency modulation theory. The sub-maxima on the high frequency side of the vNH band centre would be expected to shift to higher and those on the low frequency side to lower wave numbers on cooling the crystal; furthermore, the difference bands should show a marked intensity decrease. This result is not observed. In fact, the temperature shifts of the sub-bands are irregular (Table 2) and the intensity of the low frequency side sub-bands increases at low temperature. The vNH band sub-maxima of the isotopically substituted purine-8-d₁, on

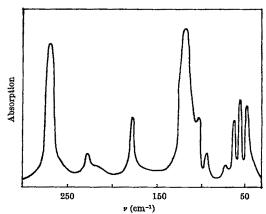

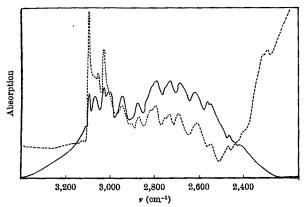

Fig. 1. Far infrared spectra of purine at liquid nitrogen temperature; nujol mull.

2. Infrared spectra of purine (—) and of partially deuterated purine-7-d₁ (....); NH/ND=10/90. Mulls in 'Fluorolube'.

the other hand, should not vary appreciably in either position or intensity, because the lattice frequencies do not shift and the NH..N bond remains unaltered. In fact, the centre of gravity of the vNH band of purine-8-d1 has the same frequency as that of purine; its structure, however, is different. There are only six well defined subbands and their frequencies differ considerably from those of purine (Table 2). Even more profound changes are observed in the structure of the vND bands of purine-7-d1 and purine-7,8-d₂, which show only two or three sub-bands while their lattice frequencies vary very little (our unpublished results).

We therefore conclude that the experimentally observed lattice frequencies, which include hydrogen bond vibrations, do not seem to determine the sub-band structure of the vNH absorption of purine and we must look for other reasons. It has been shown recently for solid alcohols that the splitting of the vOH band is caused by nearest neighbour coupling of adjacent OH groups and that this is the predominant reason for band broadening. In the case of purine, splitting of the vNH band into three infrared active components (A_1, B_1, B_2) may be expected for the crystal and two (nearest neighbour coupling) for the isolated chain approximation. We have investigated the infrared spectrum of a mixed crystal containing 90 per cent purine-7-d, and 10 per cent purine. stretching vibration can then be considered as decoupled and the structure of the vNH band is expected to be simpler. It turns out, however, that this is not the case; essentially the same sub-bands as for purine are observed in the spectrum (Fig. 2). This indicates that the chief submaxima belong to an isolated NH..N system.

The assumption that the sub-bands are caused by the overtones and combinations of internal vibrations in Fermi resonance with the NH stretching mode, as found for imidazole4, seems to be the most satisfactory. An assignment of the sub-bands is not given, but their behaviour with different isotopic species is consistent with the fundamentals which may give rise to binary combinations in the 3,200-2,200 cm⁻¹ region.

Solvation Forces in Soap Films

THE stability of soap films and colloidal dispersions involve the same forces, thus leading to the same type of curves for potential energy plotted against distance. Such curves frequently show two minima¹ (Fig. 1). Stabilization in the secondary minimum at relatively large inter-particle separation distances (102-103 Å) is controlled by electrostatic double layer repulsion forces and this region of the curve has been investigated in some detail² for aqueous soap films in air. Stabilization in the primary minimum at small separation distances (10-20 Å) has been considered to be governed by a short range repulsive force as a result of interaction between solvation layers a few molecules thick which are associated with the two flanking surfactant monolayers3. Any closer approach of the two interfaces entails desorption which manifests itself as a rapidly increasing repulsive force as successive solvation layers are removed4. Because of the lack of specific data, this short range repulsive force is conventionally represented in the potential energy diagram by a very steeply rising curve at a certain critical separation distance¹, implying that primary minimum, or Perrin, films must be subjected to very large pressure differences before they can be further thinned. One method for investigating this region of the potential energy curve is to measure film thickness as a function of relative water vapour pressure.

Equilibrium film thicknesses can be conveniently determined by an optical reflexion method⁵ using the appropriate three layer optical model^{6,7} to interpret the photometric data. The equilibrium thickness of vertical black films, formed from aqueous solutions of decyltrimethylammonium decyl sulphate (5×10-4 molar) containing varying amounts of sodium bromide (0.05-2 molar), has been determined optically, in the first instance for films in contact with bulk solution at their lower meniscus.

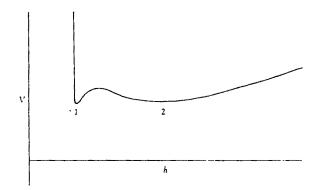

Fig. 1. Schematic representation of the total potential energy (V) per unit area of a vertical soap film as a function of thickness (h) at an arbitrarily low ionic strength. 1 is the primary, 2 the secondary, minimum,

The films were formed on a rectangular $(2 \text{ cm} \times 5 \text{ cm})$ glass frame mounted within a glass vessel which was totally submerged in a water thermostat at 25° ± 0.01° C. The electrolyte concentrations were chosen to give freedraining "mobile" films. The variation in total film thickness (h) with electrolyte concentration is shown in Fig. 2. An isolated film, supported on the same glass frame, rapidly attained isopiestic equilibrium with a bulk solution placed in the same vessel. Thus starting with a film, formed from a bulk solution containing 0.05 molar sodium bromide, the thickness could eventually be reduced to 46 Å when a saturated solution of sodium bromide $(p/p_0=0.577)$ was introduced into the system. The changes in thickness with varying water vapour pressure were shown to be reversible for single films which had lifetimes of the order of several days.

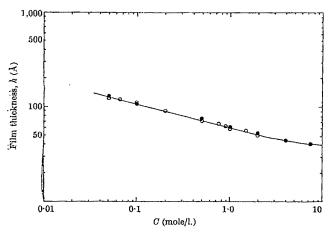

Fig. 2. Equilibrium thickness (h) of black foam films as a function of sodium bromide concentration (C) of bulk solution. \bigcirc , Equilibration through the bulk phase; \bigcirc , equilibration through the vapour phase.

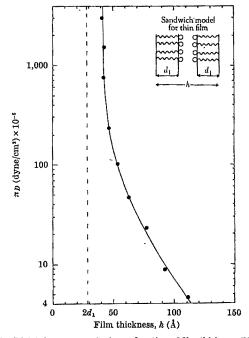

Fig. 3. Disjoining pressure (π_D) as a function of film thickness (h). The thickness of two surface layers, $2d_1 = 28$ Å.

Thicknesses are in good agreement with the previous equilibrium measurements (Fig. 2). The introduction of a series of saturated salt solutions of progressively lower partial pressures down to $p/p_0 = 0.11$ has enabled film thicknesses at these low water activities to be measured. Even though the water vapour pressure was considerably lower than the value for saturated sodium bromide, film lifetimes at the lowest partial pressure which were studied were of the order of 3 h. Achievement of these low thicknesses by the hydrostatic compression method² would require pressures in the range 10²-10³ atmospheres.

In describing the thermodynamics of thin film systems, Derjaguin has introduced the concept of a disjoining pressure^{8,9} which results from the net effect of the various surface forces operating in the thin layer. At equilibrium, the internally generated film pressures must balance the externally applied osmotic pressure. Thus the removal of water from a thin film to the infinitely thick pure liquid phase as standard state can be related to the disjoining pressure (π_D) by

$$\pi_D = -\frac{RT}{v} \ln (p_h/p_0) \text{ dyne em}^{-2}$$

where R is the gas constant, T the absolute temperature. v the partial molar volume of water, p_h the vapour pressure of the film and p_0 the vapour pressure of pure water. Fig. 3 shows that at high pressures the total film thickness (h) as a function of π_D tends asymptotically to a limiting value of 40 Å corresponding to an aqueous core thickness of 12 Å (ref. 7). These results clearly indicate the existence of an equivalent strong repulsive force which prevents film collapse at this limiting equilibrium thickness. magnitude of this force is of the correct order to permit its identification with that required for desolvation4.

These experiments have thus demonstrated the equilibrium nature of these very thin Perrin films and the importance of short range solvation forces in determining their thickness.

The Elovich Equation in Chemisorption Kinetics

THE equation first proposed by Roginsky and Zeldovich¹ but now generally known as the Elovich equation has been extensively applied to chemisorption data2,3. The equation is

$$\frac{\mathrm{d}q}{\mathrm{d}t} = a\mathrm{e}^{-aq} \tag{1}$$

where q = amount of gas chemisorbed at time t and aand a are constants.

The most common method of determining a and α involves the integrated form of equation (1)

$$q = \frac{2 \cdot 3}{\alpha} \log (t + t_0) - \frac{2 \cdot 3}{\alpha} \log t_0 \qquad (2)$$

where

$$t_0 = \frac{1}{\alpha a} \tag{3}$$

A value of t_0 is chosen to linearize a plot of q against log $(t+t_0)$. The gradient of this plot gives a value for α , and a can then be calculated from equation (3).

It should not be forgotten that using equation (2) in this way is merely a graphical method of curve analysis. The acid test of any method of calculating a and α values is the ability of these values to reproduce the experimental data when applied to equations (1) or (2). This test has seldom been applied to published Elovich parameters. I intend to show that the accepted method of using equation (2) often leads to a and a values which do not reproduce experimental data, and to describe a modified analysis.

The calculated a value should equal the experimental rate at t=0 (equation (1)) but in most published analyses this is not the case². This has been attributed²⁻⁴ to the presence of a fast initial uptake which does not follow

equation (1). Nevertheless, t_0 values are selected to linearize q against log $(t+t_0)$ plots over the entire course of chemisorption. In my opinion, it is quite wrong to impose linearity on a section of the integrated plot where equation (1) is believed not to apply; this will result in an incorrect choice of t_0 and thus to incorrect a and α values. A better approach would be to determine the extent of the rapid initial stage and then to choose a t_0 value giving linearity only over the later stages which do obey Elovich kinetics. This approach has already been successfully adopted by Ritchie and myself5, using the following method.

Despite the imprecisions in computing rates from q against t curves, the linearity of \log_{10} (dq/dt) against q plots (equation (1)) may be taken as at least a qualitative test of the adherence of data to Elovich kinetics. This test involves no choice of a disposable parameter, and if such a plot is not linear at any stage it will be wrong to choose a t_0 which linearizes the integrated plot over that stage. Various photoadsorptions on titanium dioxide were found to follow parabolic kinetics

$$(q+q_0)^2 = kt + q_0^2 (4$$

where k and q_0 are constants, over their initial stages. Plots of $\log_{10} (dq/dt)$ against q were linear only over subsequent stages. Elovich parameters were calculated by taking zero time as the time at which Elovich kinetics began to apply and then choosing t_0 to linearize the integrated plots only from that time onwards. calculated a values then agreed with the experimental rates at the times of change-over from parabolic to Elovich kinetics, that is, at t=0 on the new time scale.

I have now applied such an analysis to selected chemisorption data from the literature. The chemisorption of oxygen on carbon films6 and on metal chromites7, of hydrogen on chromic oxide8 and of iodine on graphite8 followed parabolic kinetics (equation (4)) over their initial stages, and Elovich kinetics over their later stages. In other cases, for example, oxygen on nickel¹⁰, nitrogen on Fe-Al₂O₃-K₂O (ref. 11) and oxygen on carbon films (unpublished results of J. C. Orr and myself) no kinetic expression could be assigned to the initial non-Elovichian chemisorption. In still other cases12, the complete linearity

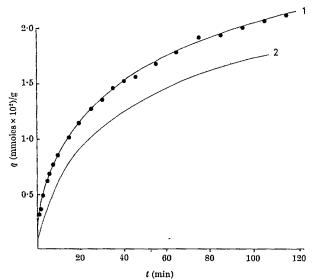

Fig. 1. Points represent experimental data? for chemisorption of iodine on graphite at 400° C.

Curve 1. t=0 to t=7 $(q+q_0)^2=kt+q_0^2$, k=750 (mmoles $\times 10^2$)?/min, q_0 negligible, t=7 to t=20, Elovich kinetics, a=1.76 (mmoles $\times 10^3$ /g)⁻¹, $q_0=12$ min. $t_0 = 12$ min. t = 20 onwards, Elovich kinetics, $\alpha = 1.57$ (mmoles $\times 10^2/g)^{-1}$,

Curve 2. Elevich over entire chemisorption, $\alpha = 1.76$ (mmoles $\times 10^2/g)^{-1}$,

of \log_{10} (dq/dt) against q plots showed that the chemisorptions were Elovichian over their entire course.

In all cases there was satisfactory agreement between avalues and the appropriate experimental rates. The α values from integrated plots agreed with the less precise values determined from \log_{10} (dq/dt) against q plots (gradient -0.434α).

Abrupt changes of slope are a feature^{2,3} of many integrated Elovich plots. The q values at which "breaks" occur depend on t_0 and thus are different when the modified analysis is applied. The a values of second and subsequent Elovich sections agreed reasonably with the experimental rates at the beginning of the sections when they were calculated from

$$a = \frac{1}{(t_0 + t^*)\alpha} \tag{5}$$

where α was obtained from the gradient of the section and t^* is the time for which previous Elovich section or sections had been in force. No mechanistic significance is yet attached to this empirical observation.

Only in a few cases¹² were Elovich kinetics followed over the entire chemisorption. There the accepted method of analysis gave parameters which reproduced the data. In all other cases⁵⁻¹², a and α values obtained by the present modified analysis described the experimental data accurately, in contrast to those obtained by linearization of integrated plots over the entire chemisorption. This situation is exemplified in Fig. 1.

Because values of a and a have featured in chemisorption models^{2,4} and in activation energy calculations² it is important to obtain reliable values of these parameters. It seems that many values quoted in the literature may be suspect.

I am grateful to the authors of refs. 6, 9, 10 and 12 for sending me copies of their original experimental data.

MOLECULAR STRUCTURE

Molecular Structure of p-Bromocarbobenzoxy-Glycyl-I-Prolyl-I-Leucyl-Glycine

WE have studied by X-ray analysis a series of oligopeptides, such as carbobenzoxy-Gly-Pro(OH), carbobenzoxy-Gly-Pro-Leu(OH), carbobenzoxy-Gly-Pro-Leu-Gly(OH) and carbobenzoxy-Gly-Pro-Leu-Gly-Pro(OH), which were prepared in order to examine the relationship between the structure of collagen and the substrate specificity for the enzyme reaction of collagenase, and have already reported some of the results1-3. Recently, the threedimensional analysis of the tetrapeptide, p-bromocarbobenzoxy-Gly-Pro-Leu-Gly(OH), has been almost completed and a unique conformation was found in its structure.

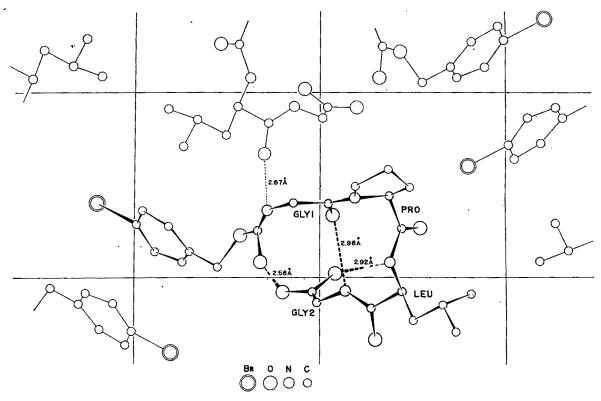

Fig. 1. Part of the crystal structure of the peptide, looking down the b axis.

The peptide chain, shown in Fig. 1, is folded back at the proline and leucine residues so as to form the intramolecular hydrogen bond (2.96 Å) between NH of Gly(2) and O of Gly(1). The conformation of the peptide backbone of this molecule is very similar to those of cyclohexaglycyl⁴ and the cyclic hexapeptide in ferrichrome-A (ref. 5). The same type of hydrogen bond has been found in these cyclic hexapeptides.

The striking feature of this peptide is that, unlike other peptides^{6,7}, it has the $C\alpha$ —H bond cis to the C'=O bond of the proline residue⁶. This may have something to do with the inactivity of this peptide to the enzyme collagenase. Both the intramolecular hydrogen bond and the conformation of the proline residue seem to be important for the stabilization of this folded structure.

The hydrogen bond, 2.92 Å, between N of the Leu residue and the carboxyl group of Gly(2) of the next upper molecule along the b axis may also play an important part in the structure. The side view of the molecule is shown schematically in Fig. 2. The terminal Gly(2) residue goes down, and one of its oxygen atoms makes a very strong hydrogen bond of 2.56 Å with the carbonyl oxygen atom of the carbobenzoxy group of the lower next molecule. Thus, by way of the strong hydrogen bond, an endless chain of the peptides is made up parallel to the b axis, and the chain as a whole looks like a somewhat deformed helix.

The dimensions of the peptide linkages are very similar to those given by Corey and Pauling⁹. The angles of rotation in the peptide backbone are listed in Table 1. The dihedral angles between neighbouring peptide linkages are 84° , 73° and 103° . The *p*-bromocarbobenzoxy group

Table 1. INTERNAL ROTATION ANGLES IN THE PEPTIDE BACKBONE

Residue	$\varphi(N-C_{\alpha})$	$\psi(G_{\alpha}-C'$
Gly(1) Pro Leu Gly(2)	269° 117 74 74	351° . 151 195

The definitions for these internal rotation angles are those given by Edsall et al. 10. Those in Pro-70 in lysozyme 11 are: $\phi=132\cdot0^\circ$ and $\psi=141\cdot4^\circ$.

seems to have little influence on the conformation of the peptide backbone.

The crystal data of p-bromocarbobenzoxy-glycyl-l-prolyl-l-leucyl-glycine, $C_{23}H_{31}N_4O_7Br$, are: $a=14\cdot25$, $b=6\cdot21$, $c=29\cdot67$ Å, space group $P2_12_12_1$, and Z=4. The X-ray intensity data of the reflexions with the spacing

glucometasaccharinic acid (pathway B). All the intermediates and final products were identified by paper chromatography and paper electrophoresis.

This scheme for the alkaline degradation of glucose-6phosphate is strikingly similar to the well known anaerobic enzyme metabolism of carbohydrates3. Glucose-6-phosphate is produced in muscle either by the action of muscle hexokinase on glucose, or by the glycolysis of glycogen. through the intermediate formation of an a-glucose-1phosphate. In muscle, glucose-6-phosphate reversibly isomerizes into fructose-6-phosphate, a reaction which is catalysed by the enzyme isomerase, in a way analogous to the alkaline isomerization (pathway A) and probably also involving an enediol anion intermediate⁴. In glycolysis, however, the splitting of fructose-6-phosphate to the three-carbon compounds initially requires its phosphorylation by adenosine triphosphate to fructose-1,6-diphosphate (enzyme-phosphofructokinase), which only then splits to dihydroxyacetone phosphate and glyceraldehyde-3-phosphate. Several further steps are involved until the final conversion into lactic acid. A very similar scheme occurs in the alcoholic fermentation of glucose (the Embden-Meyerhof pathway), except that the final product is ethanol and carbon dioxide. There is no known metabolic analogue, however, to the reaction chain B leading to 6-phosphoglucometasaccharinic acid.

The similarity between the alkaline and the metabolic degradation seems too close to be a coincidence. It suggests that the metabolic pathways are earlier in evolution than are the enzymes which catalyse these pathways. Astronomical evidence tells us that the atmosphere of primitive Earth must have been reducing, its main components having been hydrogen, ammonia, methane and water. Oceans and lakes in contact with such an atmosphere must have been alkaline. Such alkaline conditions are thus similar to those shown to cause the alkaline

degradation of glucose-6-phosphate.

We thank Drs D. Chipman and W. P. Jencks for stimulating discussions.

BIOGENESIS

Chemical Evolution of Carbohydrate Metabolism

CONSIDERABLE efforts have been made to trace the evolutionary pathways of carbohydrate synthesis1. To understand more completely the origin of metabolizing systems on Earth, it is interesting also to examine the evolution of the breakdown metabolism of carbohydrates.

Recent investigations have shown that the alkaline degradation of glucose-6-phosphate (above pH 8.7) proceeds without enzyme action, by several parallel and consecutive reactions, as demonstrated in the following

BIOCHEMISTRY

Rapid Isolation of Active Mitochondria from Plant Tissue

Most of the methods which have been described for the isolation of mitochondria from a variety of tissues1-3 are essentially very similar. The cells are gently disrupted in a suitable medium, the homogenate is then filtered through a coarse filter and the supernatant obtained is fractionated into nuclear, mitochondrial, microsomal(+) soluble components by differential centrifugation. The mitochondrial fraction, which is obtained by centrifugation at 5,000-15,000g for 15-30 min, is then washed and resedimented. One of the drawbacks of this conventional technique is that it is both time and labour consuming, making it impractical to isolate mitochondria from several different sources (for example, tissue receiving different experimental treatments) on the same day, or to compare the effects of different buffers, in the isolation media, on the subsequent activity of the mitochondria.

The results presented here were obtained from a series of experiments which were carried out to investigate whether it might be possible, by changing the method of filtration and centrifugation, substantially to reduce the time necessary to isolate biochemically active mitochondria from Jerusalem artichoke tubers. In all the experiments which I have described, the metabolic activity of the mitochondria was assayed at 25° C in 2.0 ml. of a medium consisting of 0.25 molar sucrose, 0.05 molar tris (pH 7.2), 0.05 molar potassium hydrogen phosphate, 0.01 molar malate, 0.1 per cent bovine serum albumin and 2 mg of mitochondrial protein (measured using biuret reagent) using a vibrating platinum electrode polarograph (G.M.E. 'Oxygraph'). The ADP: O ratio and the value for the respiratory control were measured by adding aliquots of 5 µl. of a solution containing 0.5 µmoles of ADP to the reaction medium.

Experiments were then carried out with the aim of significantly accelerating the isolation procedure. method of isolating mitochondria similar to that described by Wedding and Black⁴ was adopted as a reliable basis for obtaining active mitochondria. This basic method of isolation takes 70 min to carry out. The results are shown in Table 1, column A. All the solutions and apparatus used in the isolation procedures were maintained at 1°-4° C. Using a stainless steel vegetable grater (holes 2 mm in diameter), 60 g of peeled Jerusalem artichoke tubers was grated in 50 ml. of a medium consisting of 0.5 molar sucrose and 0.05 molar tris (pH 7.8). homogenate was then stirred and filtered through four layers of muslin and the resulting solution was centrifuged at 3,000g for 10 min to remove cell debris and nuclei. The supernatant was then further centrifuged at 15,000g for 25 min and the pellet which formed was resuspended in 25 ml. of 0.4 molar sucrose and 0.05 molar tris (pH 7.2) using a loose fitting Teflon homogenizer. The mitochondria were then sedimented at 15,000g for 25 min, and finally resuspended in 1.0 ml. of 0.4 molar sucrose and 0.05 molar tris (pH 7.2) and their respiratory activity was measured. Columns B, C and D in Table I show the results which were obtained when the basic method of isolation was modified in various ways. In treatment B the tissue was homogenized as already described and the homogenate was then filtered through two layers of nylon fabric (mesh 50 strands/cm) (ref. 5). No precipitate was found after centrifugation at 3,000g for 10 min, so this step was omitted. Mitochondria were removed from the supernatant after they had been centrifuged at 15,000g for 15 min. The pellet was resuspended in 25 ml. of the washing medium and recentrifuged at 15,000g for a further 15 min. The mitochondria were then suspended in 1.0 ml. of medium and their respiratory activity was measured. Treatment C was similar to B except that the supernatant and the washed mitochondria were centri-

fuged at 40,000g for 5 min. In treatment D, the homogenate was filtered through the nylon fabric and the supernatant was centrifuged at 40,000g for 1.5 min. The mitochondrial pellet was not washed, but was suspended in 1.0 ml. of 0.4 molar sucrose and 0.05 molar tris (pH 7.2) and assayed for respiratory activity.

Table 1. RESPIRATORY ACTIVITY OF MITOCHONDRIA ISOLATED BY MEANS OF DIFFERENT PROCEDURES

		Isolation	procedures	
	A	\boldsymbol{B}	` <i>c</i>	D
Time elapsed during the isolation procedure	70 min	37 min	15 min	7·5 min
Total protein in the mitochondrial fraction	46 mg	32 mg	35 mg	31 mg
Rate of oxygen uptake "state 3" (µmoles oxygen/mg protein/min)	0.026	0.043	0.044	0.043
Rate of oxygen uptake "state 4" (µmoles oxygen/mg protein/min)	0.009	0.011	0.009	0.008
Respiratory control value ADP: O ratio	2·8 2·9	3·9 2·9	4·9 2·8	$5.3 \\ 2.9$

Isolation treatments were: A, filtration through muslin and sedimentation between 3,000–15,000g for 25 min, followed by washing and resedimentation at 15,000g for 25 min; B, filtration through nylon fabric and sedimentation between 0–15,000g for 15 min, followed by washing and resedimentation at 15,000g for 15 min; C, the procedure was the same as for B except that sedimentation in both cases was carried out at 40,000g for 5 min; D, filtration through nylon fabric and sedimentation at 40,000g for 1.5 min only.

The new method reduced the time taken for isolation of active mitochondria from 70 min to just over 7 min. This was achieved by more efficient filtration, by increasing the speed of centrifugation and by omitting the final washing procedure. The values for the respiratory control increased from 2.8 to 5.3 as the time taken to isolate the mitochondria was decreased. The increase in respiratory control was chiefly the result of a significant increase in the rate of oxygen uptake during "state 3" respiration, although a slight decrease was apparent in the rate of oxygen uptake during "state 4" respiration. The ADP: O ratio remained constant in all the preparations. The increase in the rate of oxygen uptake per unit of protein in the mitochondrial fraction could be the result of rapid removal of the mitochondria from the supernatant which may contain endogenous inhibitors like quinones and fatty acids. A further advantage of this rapid isolation technique is that when it is used in conjunction with a polarographic method of assay, it is possible for mito-chondria to be isolated and assayed for rate of oxygen uptake, ADP: O ratio and respiratory control can be obtained in less than 10 min, thus enabling many different samples to be compared in one day.

Determination of Free Radicals in Gamma Irradiated Proteins

THE long-lived free radicals produced by gamma radiolysis of dry proteins at room temperature have been previously studied by electron spin resonance1 (ESR). The carbon radicals which can be observed by ESR have been interpreted² as being predominantly located on glycine. Recently, the use of tritiated hydrogen sulphide as interceptor of free radicals has been proposed as a new experimental technique for determining the distribution of free radicals located on earbon atoms. The method involves exposing the gamma irradiated lyophilized proteins to tritiated hydrogen sulphide in order to form carbontritium bonds in the protein. Tritium distribution among the amino-acids can be determined by subsequent hydrolysis, amino-acid analysis and tritium counting; this measures the "secondary" free radical distribution. The terms "primary" and "secondary" free radicals refer, respectively, to (a) those radicals formed on irradiation at 77° K, and (b) those which arise from them on subsequent warming or which can be observed after radiolysis at room temperature.

In the labelling reaction, SH radicals are generated as

shown in equation (1)

$$C + HSI \rightarrow C - I + HS. \tag{1}$$

Although the bond dissociation energy of HS-H (90 kcal)⁴ is considerably lower than that of most C-H bonds, the possibility cannot be ruled out a priori that SH radicals abstract hydrogen from carbon (reaction (2))

$$C-H + HS - - C + H_2S$$
 (2)

to produce a new class of carbon radicals which were not initially formed by gamma radiolysis. This new class of radicals would not be expected to be identical with the initial class and thus could lead to an erroneous tritium distribution. Furthermore, reaction (2) could lead to a chain reaction for tritium incorporation by way of reaction (1). In order to examine the possible contribution of reaction (2) to labelling with tritiated hydrogen sulphide, we used tritiated hydrogen iodide as the radical interceptor. For this reagent, the reaction analogous to (2) (abstraction of hydrogen from carbon by iodine atoms) cannot occur because of the low bond dissociation energy of the hydrogen iodide molecule [71 kcal⁴]. This has been demonstrated by experimental work in which iodine and hydrogen iodide have been used as radical scavengers⁵.

The experimental procedures with tritiated hydrogen iodide were similar to those previously reported³ for tritiated hydrogen sulphide, with the exception that tritiated hydrogen iodide was separated from the iodine formed by self-radiolysis by two distillations from traps at the temperature of dry ice. The reaction of free radicals with hydrogen iodide can be followed by observing the electron spin resonance spectrum as a function of time. Fig. 1 shows the result of a typical experiment in which ribonuclease, gamma irradiated with a dose of 4.2Mrads at room temperature, was subsequently exposed to hydrogen iodide at a pressure of 150 torr. After 12 min. a marked decrease of the doublet peak occurs as a result of carbon radicals. After 4 h, all of the carbon radicals have reacted, leaving only the sulphur signal. The latter is caused by sulphur radicals, formed during gamma radiolysis, which do not react with hydrogen iodide.

It is important to distinguish between tritium labelling induced by β -decay of the tritiated radical interceptor (" β -labelling") and that introduced as a consequence of radical formation by gamma radiolysis ("gamma label-ling"). The extent of "β-labelling" was determined in experiments without prior gamma radiolysis, in which 20 mg of ribonuclease or chymotrypsinogen was exposed to tritiated hydrogen sulphide or tritiated hydrogen iodide. obtained from New England Nuclear Corporation, Boston. Mass. [3.0 ml. of gas containing 30 me.], for 4 h. After removal of all exchangeable tritium and after acid hydrolysis, the average specific activities (µc./mg) for ribonuclease were 0.073 (tritiated hydrogen sulphide), 0.085 (tritiated hydrogen iodide) and for chymotrypsinogen 0.038 (tritiated hydrogen sulphide), 0.078 (tritiated hydrogen iodide). The combined "γ+β" labelling was measured by irradiating the proteins with 5 Mrads in a cobalt gamma source in the absence of air (10-3 mm of mercury), and then by exposing the proteins to tritiated hydrogen sulphide and tritiated hydrogen iodide for 4 h in the conditions already mentioned. The average specific activities for ribonuclease were 0.76 (tritiated hydrogen sulphide), 0.23 (tritiated hydrogen

iodide) and for chymotrypsinogen 0.76 (tritiated hydrogen sulphide), 0.32 (tritiated hydrogen iodide). The observation that the amount of incorporated tritium is of the same order of magnitude for both interceptors is consistent with the absence of a chain reaction due to SH radicals. Because "β-labelling" with tritiated hydrogen iodide introduced tritium predominantly into phenylalanine and tyrosine, the "β-labelled" distribution must be subtracted from the observed " $\gamma + \beta$ " tritium distribution to obtain the corrected "\gamma-labelled" distribution. Fig. 2 shows the gamma distribution of tritium among the amino-acids of ribonuclease and of chymotrypsinogen when tritiated hydrogen sulphide and tritiated hydrogen iodide are used as radical interceptors. The results for each protein represent the average of two to five separate labelling experiments. The bar lengths in Fig. 2 are proportional to the normalized specific activities (NSA) of individual residues. NSA is defined as

$$\frac{S_i \times 100}{\Sigma S_i}$$

where S_t is the specific activity of a given amine-acid in counts/min/ μ mole and ΣS_t is the sum of specific activities of all of the amine-acids of the protein under consideration. There are many similarities between the tritium distributions for tritiated hydrogen sulphide and tritiated hydrogen iodide. The product moment correlation coefficient for ribonuclease is 0.68 and for chymotrypsinogen is 0.92.

From these results it follows either that hydrogen abstraction by SH radicals is not a significant process in these experiments, or that SH radicals abstract from the carbon-hydrogen bonds of the various amino-acids at relative rates which accidentally parallel the "secondary" radical distribution produced by gamma radiolysis. The second hypothesis appears to be less likely. The results with tritiated hydrogen iodide support the three major con-

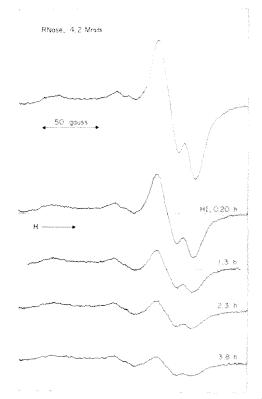

Fig. 1. Electron spin resonance spectra of irradiated ribonuclease before and after addition of hydrogen iodide. Ribonuclease was gamma irradiated (dose 4·2 Mrads) in vacuum, at room temperature (upper curve). Hydrogen iodide (150 torr) was subsequently added and spectra were recorded at different times. The curves represent the first derivatives of the absorption curves.

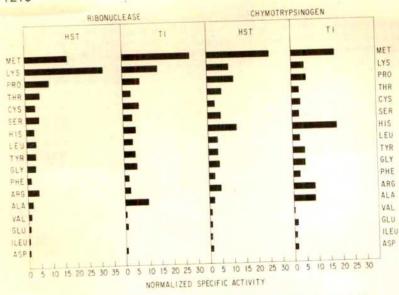

Fig. 2. Distribution of tritium among the amino-acids of ribonuclease and chymotrypsinogen using tritiated hydrogen sulphide and tritiated hydrogen iodide as radical interceptors. Bar lengths are proportional to the normalized specific activity (defined in text).

clusions previously obtained with tritiated hydrogen sulphide. First, it can be seen that tritium is widely distributed among amino-acid residues. Second, in a given protein, the specific activities vary from very high to very low. Third, the specific activity of glycine is very low, indicating that glycine does not play a special part as a free radical site in these proteins. The specific activities of certain amino-acids, however, are significantly different when the two reagents are compared. Thus the specific activity of lysine in ribonuclease labelled with tritiated hydrogen iodide is lower and that of alanine is higher than for labelling with tritiated hydrogen sulphide. It seems therefore that some distortion of distributions can occur when tritiated scavengers are employed.

We thank Dr H. Kon for electron spin resonance measurements, Dr H. A. Schwarz for helpful discussions and Miss Carole Halsey for operation of the amino-acid analyser.

Multiple Forms of Cobra Venom Phospholipase A

MULTIPLE forms of enzymes catalysing identical reactions can exist even in one tissue1. Cobra venom is a rich source of phospholipase A (phosphatide acyl-hydrolase, EC 3.1.1.4)2. This enzyme catalyses the conversion of lecithin and other phospholipids to lysophosphatides, by removal of a fatty acid residue in the second position of the phospholipid molecule³.

The haemolytic effect of phospholipase A on erythrocytes is caused by the action of lysophosphatides. A study of a cytotoxic factor from cobra venom4 which is selectively destructive to certain cells showed that at least seven cobra venom protein fractions brought about lysis of washed erythrocytes in the manner of phospholipase A.

In the present work a visual technique was developed to detect phospholipase A activity in the bands separating out after starch gel electrophoresis. The protein bands were adsorbed on paper strips which were then transferred to blood agar plates. At the end of an incubation period, clear and sharp haemolytic zones were observed, corresponding to the proteins with phospholipase A activity. Whatman 3 MM paper strips were soaked in a solution of isotonic saline containing 0.1 per cent calcium chloride because it is known that phospholipase A needs Ca++ for its activity5. strips were then dried and placed on the starch gel electrophoretic pattern for 15 min at 37° C. On removal they were again dried in air and replaced on blood agar

plates containing egg yolk emulsion as a source of external phospholipids. (The composition of blood agar plates was: 8 ml. of 6 per cent washed human erythrocytes + 0.5 ml. of 10 per cent egg yolk emulsion in 1.3 per cent agar in isotonic saline.) The plates were incubated for 15 min at 37° C. Then the paper strips were removed, but the plates were incubated for a further period and observed periodically for the appearance of clear haemolytic zones. In these conditions, the bands of haemolysis were discreet and sharp. If the strips were kept in contact with agar longer the bands became diffused and tended to coalesce. The rate of appearance of haemolytic zones may be taken as a rough quantitative measure of the amount of enzyme present.

Fig. 1a and b is a photograph and diagram of the electrophoretic pattern of cobra venom proteins obtained by the technique of Poulik⁶ (with 8 molar urea) and the corresponding haemolytic zones produced on blood agar plates. There are fourteen bands: of these, six protein fractions migrate to the cathode and eight towards the anode. Clear haemolytic zones are seen corresponding to the negatively charged protein bands. To distinguish between phospholipase A effect and the direct haemolytic factor, present in cobra venom known to cause lysis of erythrocytes without a phospholipid source, the electrophoretic patterns described in Fig. 1 were tested on blood

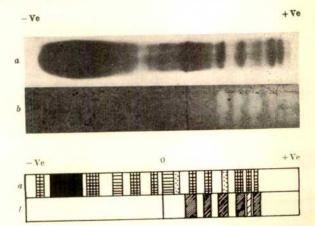

Fig. 1. Electrophoretic pattern of snake venom protein and haemolytic zones produced on blood agar plates (conditions: 200 V, 7 h, pH 8-6 and temperature 20° C). a, Cobra venom mixture (amido black); b, cobra venom mixture (haemolytic zones).

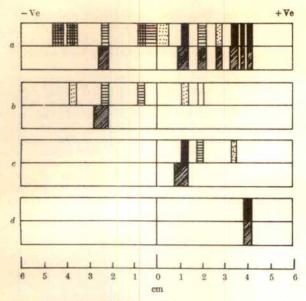

Fig. 2. Phospholipase 4 bands in purified cobra venom protein fractions (conditions as in Fig. 1). agar plates prepared without egg yolk. In these conditions, no haemolysis was produced, so the involvement of the direct lytic factor is excluded. A similar study of four other varieties of snake venom indicated that cobra venom mixture had the most multiple forms of phospholipase A. There were two zones of phospholipase A type of activity in Mamushi venom, whereas Russell's viper, Bothrops alternata and Bothrops jararaca venom showed a single band. All forms of phospholipase A

detected migrated towards the anode.

The various forms of phospholipase A from cobra venom were purified by treatment with perchloric acid in controlled conditions followed by fractionation in CM cellulose and 'Sephadex'. Fig. 2a is the electrophoretic diagram for the perchloric acid precipitate fraction which shows the presence of seven haemolytic bands in the blood agar diagram (lower half of a). One of these was found to migrate towards the cathode. Haemolytic zones produced by three active preparations obtained on further purification of the perchloric acid precipitate are given in Fig. 2b, c and d. These have distinctly different mobilities. One of the fractions (Fig. 2d) is apparently homogeneous on starch gel electrophoresis for protein and haemolytic activity. Thin-layer chromatography of products formed on incubating the fractions with lecithin showed the presence of lysolecithin and a fatty acid, confirming that the lytic activity was the result of phospholipase A.

The separation of various protein bands with phospholipase A activity could not result from artefacts produced by urea which is known to cause splitting of the protein molecules, for similar patterns were obtained in its absence. Urea was included in the starch gel because it did not affect the enzyme activity and produced sharper separation of protein bands. One of the active zones migrating to the cathode appeared only after treatment of venom with perchloric acid. This could be caused by a concentration effect because treatment with perchloric acid resulted in complete precipitation of all haemolytic activity present in the starting material, but only 50 per cent of the total protein was precipitated.

Because cobra venom is a complex mixture of several proteins, differences in mobility could have arisen by interaction of an active protein with other proteins. This possibility seems unlikely because at least three active protein fractions showing different mobilities have been separated from the crude mixture after extensive purification using ion exchange column and 'Sephadex' filtration. The mobilities of two of these compare well with the original bands observed in the crude venom, suggesting that there are at least seven different molecular species of phospholipase A of varying electrophoretic mobility in cobra venom.

We thank Dr P. J. Deoras of the Haffkine Institute for the supply of venom and Mr Khandeparkar for technical help. The Wellcome Trust gave financial aid.

Altered Duration of DNA Synthesis and Cell Cycle in Non-target Tissues of Mice treated with Oestrogen

THE effects of ovarian hormones on the cell cycle of target tissues have been extensively studied. It has been shown that high doses of oestrogens of exogenous origin can alter the duration of DNA synthesis (S phase) in target tissues when administered alone1.2 or in association with progesterone3.

The present work was undertaken to evaluate the degree of specificity of this action of oestrogen on the cell proliferation. For this purpose we studied the kinetics of the mitotic cycle of non-target tissues (namely, the intestinal crypt epithelium) in spayed mice, treated with doses of 17-3-oestradiol which, as previously shown4, reduces the duration of DNA synthesis and the length of mitotic cycle in uterine and vaginal epithelia.

Swiss albino mice, of average weight 25 g, were ovariectomized. The group of treated mice received sub-cutaneous injections of 17-β-oestradiol daily for 7 days, beginning 20 days after castration. The daily dose of hormone injected was 5 μg on days 1-3 and 7.5 μg for

the following 4 days.

On the seventh day the controls and the treated animals were subjected to the double labelling techniques to estimate the duration of DNA synthesis and the generation time of the intestinal crypt epithelium. We employed the procedure described by Maurer et al.5, using two separate injections of 3H-thymidine (1 µc./g and 10 μc./g, respectively). Autoradiographs of the labelled tissues showed two types of labelling: heavily labelled and weakly labelled nuclei. The latter corresponded to the cells which went out of the DNA synthesis phase during the interval between the two injections. number of weakly and heavily labelled nuclei was determined, and the duration of S phase was calculated from the relationship $H/W = S/t_t$ (ref. 5), where H represents heavily labelled nuclei, W weakly labelled cells, t_t the interval between the two injections (1 h in this case) and S the duration of DNA synthesis, or S phase. The labelling index (that is, the number of labelled cells/100 cells) was also measured. This made it possible to estimate the generation time (GT) by the relationship

$$\mathrm{GT} \,=\, \frac{S}{\mathrm{LI}} \,\times\, 100$$

where LI represents the labelling index.

Sections, 3–4 μ thick, were covered with Ilford K5 emulsion, by dipping the lides in the melted emulsion. The autoradiographs were exposed for 3 weeks at 4° C. After development, they were stained with haematoxylin-eosin and mounted in 'DPX' mounting medium (Michrome) for observation under oil-immersion.

As shown in Table 1, treatment with oestradiol produced a reduction in DNA synthesis time in the erypt epithelium of the duodenum, jejunum, ileum and colon.

Table 1. Effect of 17- β -oestradiol on the duration of the S phase and cell cycle in the crypt epithelium of the intestinal tract of spayed mice

()	S phase (h) Oestradiol		Generation time (h)* Oestradiol	
Organ	Control	treated	Control	treated
Duodenum Jejunum Ileum Colon	6·5 6·5 6·7 6·2	4·6 4·2 4·3 4·7	14·5 14·8 15·2 27·7	12-2 10-5 9-7 22-5

* Calculated on the basis of the labelling index.

The duration of the mitotic cycle, calculated with the labelling index, also seems to be shortened by treatment with oestrogen. This decrease in generation time is not covered by the reduction in the duration of the S phase, which indicates that at least one other phase of the cycle is also accelerated. Similar observations were made in target tissues (uterine and vaginal epithelium) of the same mice4. In that case, however, the acceleration of the mitotic cycle and the shortening of S phase were sharper than in the non-target tissues. This suggests that, as regards their action on the cell cycle, oestrogens act in the same way in both target and non-target tissues, the differences in the response being only a matter of degree.

A reduction of the mitotic cycle in a non-specific organ. the corneal epithelium, has been observed by Epifanova² in the mouse treated with oestrone. In this case, however. no alteration of the duration of the S phase is reported. If not linked to tissue characteristics, this disagreement with our results could be caused by the different concentrations of hormone used, Epifanova's being somewhat lower (2 \times 2.5 μg of oestrone). She assumed that oestrogens could act by accelerating the initiation of the DNA synthesis. Our findings suggest that higher doses of the hormone extend its effect to the S phase itself.

A similar situation seems to prevail in the case of the joint action of oestrone and progesterone. It has been observed that a higher dosage of exogenous ovarian hormones than that existing in adult virgin mice is necessary to affect the duration of DNA synthesis in the mammary gland^{3,6}. The level of endogenous hormones is, however, sufficient during pregnancy and lactation to induce such a reduction in the duration of the S phase?. During oestrus, the increase in the concentration of endogenous eestrogen parallels a reduction in the duration of the mitotic cycle in the vaginal basalis from 71 h to 25 h without alteration of the DNA synthesis time⁸. In our experiments with high doses of 17-β-oestradiol, a similar reduction of generation time (from 71 to 20 h) was observed in this tissue, but the duration of the S phase was also modified, being reduced from the 6.3 h in the controls to 2.3h in the treated mice4. This seems to be very similar to our observations in the non-target tissues.

High regional concentrations of oestrogen could be necessary to alter the duration of DNA synthesis. This may readily be attained in target tissues, because of their high affinity for the hormone. The same result can be reached in non-target organs if very high doses of oestrogen are injected, thus overcoming the low affinity of the cells for the hormone. Experiments are now in progress to test this hypothesis of a dose-response relationship in the degree of alteration of the S phase induced by oestrogen in both target and non-target

tissues. Physiological and experimentally induced variations in the oestrogen level are being studied. In such studies the double labelling technique has the advantage of making possible more instantaneous measurement of the DNA synthesis phase than the wave of labelled mitoses methods, usually used.

This work also shows that the duration of the S phase in duodenum, jejunum, ileum and colon can be reduced below the value of 6-7 h formerly considered to be nearly constant. Observations of higher durations 10,11 have already invalidated this suggestion of an approximately constant S phase duration. The present results, together with previously reported observations on a very short DNA synthesis phase 10,11, suggest that the former suggestion cannot be replaced by another a priori plausible suggestion¹⁻⁴, that the figure of 6-7 h represents an approach to the minimum time required for DNA doubling in mammalian cells.

This work was carried out under contract for Euratom and the Universities of Brussels and Pisa.

Bidirectional Transport of Radioactively Labelled Axoplasmic Components

It is well established that axoplasm moves somatofugally from the neurone cell body toward the axon terminals1. Somatofugal axoplasmic transport was first demonstrated by Weiss and Hiscoe2, who found that if a peripheral nerve was constricted the axons proximal to the site of constriction became engorged with axoplasm. Recent variations of these experiments have shown that certain axoplasmic components (acetylcholinesterase1, catecholamine storage granules3 and labelled phospholipids4) accumulate distal as well as proximal to the constriction. This tendency for axoplasmic components to accumulate on both sides of a lesion in a nerve has been interpreted as support for the idea that axoplasmic components move along the axons both from the cell body toward the axon terminals and back in the direction of the cell body.

I have studied the effect of transecting the sciatic nerve of a cat on the distribution in it of labelled axoplasmic proteins. If L-leucine-3H was injected into the vicinity of neurone cell bodies connected with axons in the sciatic nerve, the proteins within those axons were labelled, while the connective tissue surrounding the axons remained unlabelled^{5,6}. With this method the distribution of labelled axoplasmic proteins along the sciatic nerve can be analysed by measuring the amount of radioactivity present in segments of the nerve.

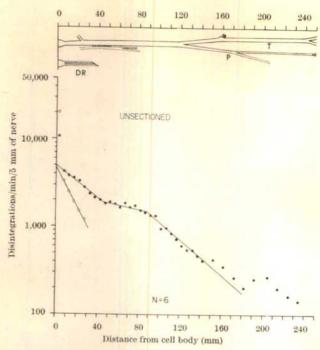

Fig. 1. The amount of radioactivity in each 5 mm segment of peripheral nerve (•) and dorsal root (○) in relation to distance from the injection site in the ganglion. The cats were killed 6 days after injection. A schematic representation of the sciatic nerve, its branches, the peroneal (P) and tibial (T) nerves, and the dorsal root (DR) illustrates the position from which the points below were obtained. N is equal to the number of segments used for each point on the curve.

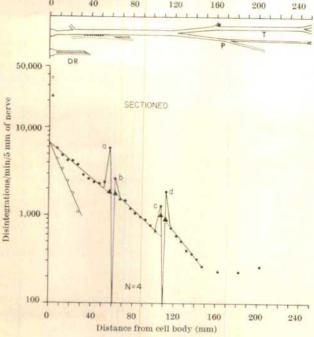

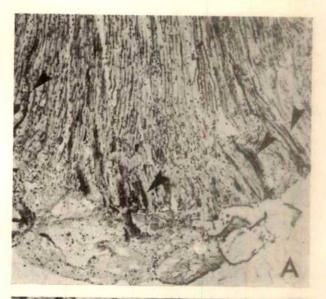

Fig. 2. Amount of radioactivity in each 5 mm segment of peripheral nerve (•) and dorsal root (○) in relation to distance from injection site in the ganglion. Sciatic nerves were sectioned bilaterally 24 h before the casts were killed 6 days after the injection of the label. The triangles represent the control value in the homologous segments of the unsectioned preparations taken from Fig. 1. The amount of radioactivity in the nerves was extrapolated to zero at the point of section.

The lumbar-7 dorsal root ganglia of five cats were bilaterally exposed by aseptic surgery and two injections of 1 μl. isotonic saline containing 5 μc. L-leucine-³H were made into each ganglion. In two cats, the sciatic nerve was severed bilaterally 60 and 110 mm from the ganglion, 24 h before they were killed. All the cats were killed 6 days after injection of the labelled compound. The

lumbar-7 ganglia and attached nerves were dissected out and cut into 5 mm segments which were then prepared either for liquid scintillation counting or for autoradiography⁵

In the unsectioned control preparations (Fig. 1), the incorporated L-leucine-"H present in the axons was distributed in the nerves along a decreasing gradient centrally and peripherally from the ganglion. In the experi-mental preparations in which the sciatic nerve was severed (Fig. 2), the decreasing gradient was interrupted by peaks of radioactivity both proximal and distal to the sites of transection. The curves from the individual sites of transection. preparations were identical to the mean curves in Figs. 1 and 2. Similar alterations in the distribution of radioactivity were also found if the sciatic nerve was severed 1 or 2 days after injection of L-leucine-3H and the animal killed 24 h later. Autoradiographs of the stumps in which increases of radioactivity occurred confirmed that the label was localized within the axons and that little or no label was present in the surrounding connective tissue (Fig. 3).

Axoplasmic proteins labelled with L-leucine-*H seem to be synthesized primarily in the neurone cell body*-7, and very little free leucine-*H is carried from the cell body into the axon*. This evidence suggests that the

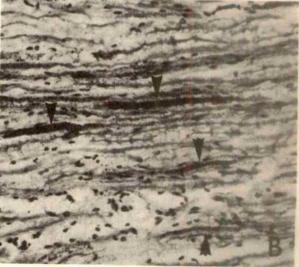

Fig. 3. Autoradiographs of the severed ends of labelled axons (arrows) in the proximal stump of the sciatic nerve, that is, equivalent to segment a in Fig. 2. A, \times 60; B, \times 200.

accumulation of label at the points of transection probably resulted from translocation of the labelled proteins which were present in the axons at the time of transection. Translocation must have occurred over a distance of several mm because the segments immediately adjacent to points a, b, c and d in Fig. 2 did not show a decrease in radioactivity which could account for the accumulation in segments a-d. Accumulation of radioactivity on both sides of the transection may indicate that some axoplasmic components containing protein are conveyed along the axon both towards and away from the cell body. It lends further support to the concept of bidirec-

tional axoplasmic transport1,3,9.

The amounts of radioactivity in the segments adjacent to the sites of transection were compared with the homologous control The mean percentage increase segments. of radioactivity in the transected segments over the control segments was: a = 211per cent; b=54 per cent; c=31 per cent; and d=117 per cent. These increases in the amount of radioactivity proximal and distal to the sites of transection are similar to those found by Miani⁴ for labelled phospholipids in the rabbit vagus nerve. Similar increases of proteins and phospholipids in the axons both proximally and distally to the lesion suggest that part of the label which accumulated in the axon stumps was bound to membranous organelles within the axoplasm. This possibility is sup-ported by the demonstration that in constricted nerves mitochondria accumulated in axons proximal to the site of constrictions, and that axoplasmic components with the dimensions of mitochondria move bidirectionally in the axons

of cultured chick spinal ganglion cells. The shape of the curves for distribution of label along the nerves in the sectioned and unsectioned preparations (Figs. 1 and 2) is similar except for the isolated segment of nerve between the points of transection. This may indicate that during the first 24 h after transection of the nerve the distribution of labelled components which are conveyed in the central or peripheral processes of the ganglion cells remains unaltered. Miani's results with labelled phospholipids support this possibility.

Bidirectional streaming in axons may be a mechanism for conveying biochemical information from the cell body into the axons and back into the cell body. Thus bidirectional axoplasmic movement could represent a feed-back loop through which the neurone cell body monitors the biochemical profile of its long cytoplasmic

Size Relation between a Chromatographic Spot and its Autoradiogram

If a chromatogram has at the origin four spots, constituting a series of concentrations of a solute $(C_1, C_3,$ C_5 , C_7) with each member of the series containing an identical amount (C*) of radioisotopic solute (radiomer), colour development after chromatography gives the expected1 near-linear relation between the area of the spot and the logarithm of its concentration, but the corresponding autoradiogram shows spots of equal size (Fig. 1). This phenomenon, which seems to oppose what might be expected intuitively2,3, has a simple explanation.

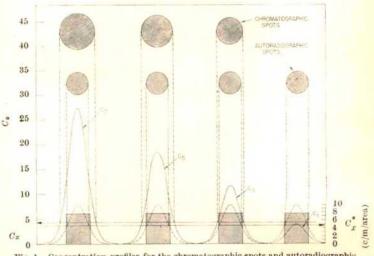

Fig. 1. Concentration profiles for the chromatographic spots and autoradiographic spots.

Consider each solute as having been spotted initially as a disk with uniform dispersion, all the disks (for each of the diverse concentrations) being of identical radius. After development for a time t, the concentration profile of solute along a diameter is given by the relation4,5

$$C(r,t) = C_0 r_0 \int_{u=0}^{\infty} J_1(r_0 u) J_0(r u) e^{-Dt u^2} du$$

where J_1 and J_0 are first and zero-order Bessel functions of the first kind, respectively, with argument u, and where ro is the initial radius of the disk, r is the radius of the spot at time t, and D is the diffusion coefficient of the solute. In our example, the corresponding profiles are shown in Fig. 1. For convenience, we consider the normal, that is, non-radioactive, solute (normer) and the radiomer as moving independently. We may then describe an independent profile for the radiomeric population, assuming its diffusion coefficient identical with that of the normeric.

We determine experimentally a concentration $[C_x]$ of the solute which provides the visual limit of detection following colour development, and similarly the concentration of radiomer $[C_x^*]$ necessary to produce visible film blackening within a time period t_x . Then $[C_x]$ and $[C_x^*]$ define the "edges" of the spot.

Because of the initial concentration differences in each C_1 , the radius (r_x) at which C_x is found after chromatography will usually be different for each spot, that is, $r_{c_1} \neq r_{c_2}$, etc. This merely states that the chromatographic areas of the different spots will be different. Because the radiomeric concentrations were identical, however, the corresponding r_c *s will be identical (Fig. 1).

Two corollaries follow. (1) Usually, C_x and C_x * will not be identical, that is, the sensitivities for recognition of colour in the development of a solute will not be the same as that for blackening of a film (the latter being a timedependent process). The autoradiogram of a radioactive solute therefore will not usually coincide in all details with its chromatogram. (2) The value of r_{cx}^* will vary as a function of time (for any particular film and condition of development). Consequently, r_c and r_c^* can be made to coincide.

Nitrogen Compounds as Factors of Embryogenesis in vitro

In previous experiments1,2, either one of the two inorganic nitrogen compounds, potassium nitrate and ammonium nitrate, could cause the formation of embryos in tissue cultures from Daucus carota. This was most clearly demonstrated with a medium (Mw) containing White's nutrient3, 2 per cent sucrose and 5×10-8 g/ml. of 2,4dichlorophenoxyacetic acid (2,4-D). Mw could be converted from a "non-inductive" to an "inductive" form by the addition of either 4.16 g/l. of potassium nitrate or 1.65 g/l. of ammonium nitrate. The same effect, that is embryo formation, in the presence of a certain concentration of one of these compounds, was also obtained if a second medium (Ms) was used which differed from Mw only in the composition of the major and minor elements. Instead of White's salts and trace elements, MS contained those of the formula developed by Murashige and Skoog4. One of the problems left by these results is: why do the two different nitrogen compounds have a positive effect on embryogenesis in vitro?

Now and in previous experiments, freshly isolated tissues of the cambial area from two commercial varieties of carrot (cultivars: 'Rote Riesen' or 'Lobbericher Futterrüben') were used. They were always transferred after 4 weeks of culture and kept in the dark at a temperature of $28 \pm 1^{\circ}$ C. To estimate embryo formation the number of cultures producing embryos were expressed as percentage of the total number of cultures. Only tissue cultures forming mature embryos with cotyledons, that is, embryos beyond the heart stage, were recorded.

First, it was shown that the amount of nitrogen in the medium is important in the induction of embryogenesis. Although Mw contained 3.2 mmolar of nitrogen in the form of potassium nitrate and calcium nitrate, this was not sufficient. When, however, the nitrogen content of this medium was raised by addition of either larger amounts of potassium nitrate (13.8, 20.6 or 41.2 mmolar) or of ammonium nitrate (20.6 mmolar) embryos developed in approximately 50 per cent of the cultures receiving a high concentration of nitrogen (44.4 mmolar) and in 10 per cent of those receiving a low concentration of nitrogen (23.8, 17.0 mmolar, Table 1). The importance of the concentration of nitrogen in the nutrient could also be shown with Ms. In this case, a reduction from 60.0 mmoles/l. of nitrogen to 1.5 mmolar resulted in the loss of the capacity of the carrot cells to form embryos.

Table 1. DEPENDENCE OF EMBRYO FORMATION IN TISSUE CULTURES FROM Daucus carota ('ROTE RIESEN') ON THE NITROGEN CONTENT OF THE MEDIUM

Medium Nitrogen conc.	Mw	Mw+ NH ₄ NO ₃	Mw+KNO _s	Mw+KNO _a	Mw+KNO _x
(mmolar)	3.2	44-4 *	44-4	23.8	17-0
		Percentage o	f cultures pro	ducing embry	08
After 12 weeks After 16	0	28	13	3	0
weeks	0	49	40	10	10

Each value represents the result of at least two sets of experiments with sixteen to forty-two cultures. The control was White's medium (M=) with no embryo production.

Embryo formation also occurred if 41.2 mmolar glutamic acid (Fig. 1) or a mixture of amino-acids (Edamin, 60.0 mmolar total concentration of nitrogen) was added to Mw instead of potassium nitrate or ammonium nitrate. This confirms earlier reports5,6. The fact that there was no qualitative difference between the capacity of oxidized and reduced nitrogen to induce embryos (Fig. 1) demonstrates clearly that it is the concentration and not the form of the nitrogen in the medium which is important. These results are contradictory to the statement of Halperin and Wetherell⁷ that for embryogenesis in vitro ammonium is a requirement which cannot be replaced by potassium nitrate or by amino-acids.

Finally, some of our results showed that as well as the amount of nitrogen the potassium and ammonium ions might be partially responsible for the effects of potassium and ammonium nitrates. Carrot tissues grown, for example, on Ms with a low nitrogen content (6.0 mmolar) and potassium (3.1 mmolar) hardly ever formed embryos. These appeared, however, in 50 per cent of the cultures receiving the same low nitrogen level of 6.0 mmolar,

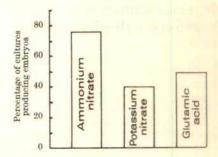

Fig. 1. Embryo formation in carrot cultures (cultivar 'Rote Riesen') on Mw (control 3-2 mmolar nitrogen) 16 weeks after addition of equivalent amounts of nitrogen (41-2 mmolar) in the form of ammonium nitrate, potassium nitrate or glutamic acid. Each column represents the average value of two sets of experiments with twenty cultures.

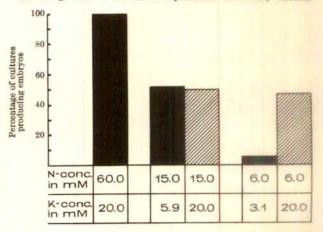

Fig. 2. Effects of different concentrations of nitrogen and potassium in Ms on embryo formation in carrot cultures (cultivar 'Rote Riesen') after 16 weeks. Each column represents the average of two sets of experiments with forty cultures. Concentrations of nitrogen and potassium were decreased by reducing both the potassium nitrate and the ammonium nitrate originally present in Ms. The concentrations of potassium were increased to the original level by adding potassium phosphate.

provided that the original concentration of potassium (19.9 mmolar) in Ms was restored by adding potassium phosphate (Fig. 2). This effect of the KH2PO4 was only evident with a low concentration of nitrogen (6.0 mmolar); it did not appear with higher concentrations (15.0 mmolar; Fig. 2). A further indication that cations can be important came from other experiments employing ammonium ions. Tissues growing on Ms without ammonium nitrate produced few or no embryos, but these were formed readily after the addition of a small amount of ammonium chloride (2.1 mmolar). This stimulatory effect of cations on embryogenesis can be causally related either to the permeability of the carrot cells to the two cations as well as to the nitrate anion, or to the activities of enzymes involved in the conversion of nitrogen in vivo, or to both of these.

Abscission induced by Betahydroxyethylhydrazine: Conversion of Betahydroxyethylhydrazine to Ethylene

BETAHYDROXYETHYLHYDRAZINE (BOH) accelerated the abscission of detached fruits and leaves in closed containers. Evidence is presented which indicates that ethylene, formed from BOH, was the abscissing agent. Ethylene¹, BOH² and auxins³ are all active in the induction of flowering in pineapple. Burg and Burg4 have proposed that ethylene, resulting from the NAA treatment, was active in causing flowering. Our data suggest the activity of BOH and other related hydrazines is by means of ethylene.

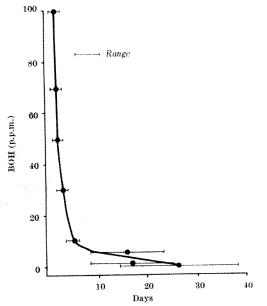

Fig. 1. Summary of abscission responses of 'Navel', 'Valencia', 'Hamlin', and 'Sweet' oranges, grapefruit and lemon fruit.

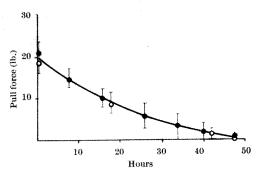

Fig. 2. Force to separate fruit from the stem, 'Navel' orange 100 p.p.m. BOH in closed chamber. Population distribution 95 per cent interval.

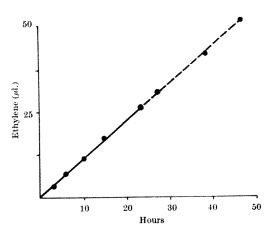

Fig. 3. Ethylene from BOH liquid (——) and 50 per cent aqueous solution (----) under reduced pressure.

For the abscission trials, eitrus fruits with about 2 in. of stem were removed from the tree, immediately brought to the laboratory and either placed in a desiccator with the stems immersed in water or set up individually in test tubes and enclosed in a polyethylene bag.

Ethylene analyses were done on a Wilkins model HY FI' gas chromatograph equipped with a hydrogen flame detector and a 1/8 in. by 2 ft. activated alumina column at ambient temperature. The sensitivity of the gas chromatograph was 1.9×10^{10} mV/mole of ethylene. The BOH samples tested were a 70 per cent field formulation solution (Olin Matheson Chemical Co.) and a research grade sample (Aldrich Chemical Co.).

Concentrations of 50-1,000 p.p.m. BOH in water induced abscission of oranges, grapefruit and lemons in less than 3 days (Fig. 1). Concentrations of 10 and 25 p.p.m. caused intermediate rates of abscission, while 5 p.p.m. or less did not accelerate abscission over the controls. The lowest concentrations showed the normal variability in abscission response which was typical of the control tests. The speed of the abscission response is shown by the rapid reduction in pull force (Fig. 2) after treatment with BOH. Within 15 h of treatment, the pull force was reduced by about 50 per cent. The force necessary to separate the stem from the fruit was measured with a constant-rate, gear driven, pull device with a meter.

When BOH was sprayed on fruits still attached to the tree and open to air circulation, there was no acceleration of abscission. This factor, plus the speed of the reaction in a closed container, made us suspect a gas effect. To check this possibility, detached fruit were placed in a desiccator with their stems in water and adjacent to an open beaker containing 1,000 p.p.m. aqueous BOH. Thus the only contact between the fruit and the BOH was the atmosphere. These fruits also abscissed in less than 60 h, and analyses of the gaseous phase confirmed the presence of ethylene. Sampling the atmosphere over a BOH

solution (from both chemical companies), contained in a test tube sealed with a serum cap, showed the presence of ethane, methane and ethylene. The identity of the ethylene was confirmed by the presence of its uniquely shaped intense absorption band at 949 cm⁻¹ in the infrared spectrum of this gas. Neither of the alkanes is physiclogically active in abscission, but ethylene is probably more active than any chemical known. It seemed logical to conclude that the ethylene responsible for abscission must have come from the aqueous BOH solution.

To confirm that ethylene was not just a soluble contaminant but was actually produced by BOH, we studied the amounts and rates of ethylene produced. The concentration of BOH in the solution did not seem to affect the fractional amount of ethylene produced in closed vessels and the reaction stopped when about 1.4 per cent of the BOH had been converted to ethylene. When the ethylene was removed by attaching gas sampling tubes under reduced pressure, ethylene production continued at the rate of 1.08 μ l./h (Fig. 3). The fact that the rate of ethylene production was constant shows that the ethylene was not a contaminant.

Table 1. EVOLUTION OF ETHYLENE FROM BOH SOLUTIONS (SEE TEXT FOR

Test DETAILS)	Ethylene evolved/24 h (moles \times 10 ⁻⁶)	Per cent conversion of BOH to ethylene
I, 50 mg/l. BOH solution I, 100 mg/l. BOH solution (pH 8·5) II, 100 mg/l. hydrochloric acid salt BOH	2-25 4-15 0-36	1·4 1·3 0·1
(pH 4-3) II, 100 mg/l.	4.61	1.4
I. Duplicate samples. II, Quadrupli	cate samples.	

An interesting biological implication of the conversion of BOH to ethylene is its pH dependence (Table 1). At pH 4.3, which would be typical of citrus fruit, the rate of conversion is only 10 per cent of the rate at pH 8.5. This would sharply reduce the ethylene production from BOH which has been absorbed by the fruit, and may partially explain the complete lack of activity of BOH

when sprayed on trees in the field.

From a physiological standpoint it seems clear that the action of BOH in citrus fruit abscission was dependent on its conversion to ethylene. N-amino morpholine, another hydrazine active in forcing the flowering of pineapple, also evolves ethylene. Because the only hydrazines which are active in inducing flowerings are those with two carbon units like BOH, it seems probable that their action is also by means of conversion to ethylene. In fact, any effect of an aqueous BOH solution becomes a potential ethylene effect. For example, Reeds clearly demonstrated that tryptamine oxidation is inhibited by BOH. Although

Fig. 4. Proposed mechanism of ethylene formation from BOH.

his data and subsequent studies7 on tryptamine oxidation inhibition by B-995 (dimethyl succinamic acid) strongly support direct action of the hydrazines, our data pose the question of the effect of ethylene on the system.

The nitrogenous products from the thermal decomposition of BOH have been identified by Howard* as methyl hydrazine, ammonia and hydrazine. (Olefinic hydrocar-

bons were not investigated.)

A reasonable mechanism for the molecular rearrangement of the BOH molecule to yield ethylene can be proposed which uses an additional carbonyl reagent such as an aldehyde or ketone as a catalyst (Fig. 4). We have tentatively identified formaldehyde as being present in these solutions by gas chromatography.

In summary, BOH has been found to induce abscission of citrus fruit explants, and this abscission has been correlated with ethylene formed from the decomposition of the BOH. A mechanism for the conversion of BOH is

proposed.

PHYSIOLOGY

Effect of Hydrocortisone on the Closure of Palatal Shelves in vivo and in vitro

SINCE the first experiments of Fraser and Fainstati in 1951, it has become clear that cortisone induces cleft palate in mice when administered before the closure of the palatal shelves. Certain direct and indirect effects on the palatal tissue have been suggested, including the effect of cortisone on the turnover of the

amniotic fluid2-4. Harris4 postulated that oligohydramnion, resulting from maternal cortisone treatment, affects the normal development of the palatal region by constricting the embryo. Recently, however, Fraser et al. have compared the amount of amnietic fluid in embryos treated with cortisone with and without cleft palate. No differences were detected and the results seem to rule out the possibility that oligohydramnion plays a part in the genesis of cleft palate.

Fraser^{6,7} has put forward another hypothesis for the mechanism of the genesis of cleft palate and the interplay of genetic and exogenous factors in this process. The hypothesis is based on findings which show that closure of the shelves takes place later in the course of development in strains susceptible to exogenous teratogens than in those which are comparatively resistant to such factors*.

Accordingly, there might be a certain critical time (threshold), determined by the general development of the embryo, beyond which the shelves are no longer able to fuse (perhaps because of the advanced stage of development of the head and the palatal defect). An exogenous teratogen may delay the development of the palatal processes and bring it beyond this threshold. Because of the biological variation of the timing of this development within each strain, the delay of the process may bring either some or all of the embryos beyond the threshold. In susceptible strains where the normal closure takes place relatively late as compared with the general stage of development, the threshold is closer and the shift needed for demonstrable effect consequently smaller, whereas in a resistant strain the closure is usually completed well before the threshold. The hypothesis thus suggests that palatal tissues of all embryos would respond similarly to the teratogen, but as a result of genetic differences in the timing of developmental events the manifestation per cent of consequent malformations varies.

We felt that this hypothesis could be tested experimentally using organotypic tissue culture methods9-13. Accordingly, in a certain population with an in vivo manifestation below 100 per cent, an invariable effect would still be expected on all palate shelves in vitro. Instead of using an inbred strain of mice, a random-bred strain was chosen because greater variations of the indidivual responses would be expected in vivo but not in vitro. Random-bred Swiss albino mice were used. These were fed freely before and during the experiment. The in vivo experiments were performed according to the scheme of Pinsky and Digeorge¹⁴. Four milligrams of hydrocortisone ('Solo-Cortef', Upjohn) was injected intraperitoneally on days 11–14. The mothers were killed on day 19, and the embryos were analysed under a dissecting microscope. For in vitro studies, the palatal regions of 13-14 day embryos were dissected in one block, and cultivated in a modified Trowell type culture15. The culture medium was essentially a chemically defined one designed by Biggers et al.16, but earlier experience with bone culture had suggested the importance of adding ascorbic acid in a concentration of 5 µg/ml. (refs. 17 and 18). In vitro development of the secondary palate was followed under a dissection microscope by daily camera lucida drawings and through subsequent histological examinations of the explants. The quantitative calculations given in the results are based on a planimetric determination of the cleft from the drawings.

Following the experimental design, a pilot study revealed an incidence of 27 per cent of cleft palate malformation in our mice in vivo. The result of a consequent experiment is given in Table 1. Preliminary in vitro studies on palatal shelves from untreated embryos indicated that their viability was good in the culture conditions and that a complete fusion of the shelves took place in 3-4 days, depending on the age of the donor embryos. Subsequently, hydrocortisone was added to such cultures in concentrations ranging from 0.001 to 20.0 $\mu g/ml$. The hormone was added at the onset of the experiments and the same culture medium was used throughout the 3-12 day experiments. The volume ratio tissue/medium was approximately 1:50. Neither the lowest nor the

highest concentrations of cortisone showed a uniform effect on the growth and fusion of the palates and were omitted in the final series. Concentrations between 0.1 and 0.01 µg/ml. significantly retarded the fusion of the palatal shelves as seen in Table 2 and Fig. 1. The completion of the fusion was usually postponed by 1-3 days, but it should be stressed that a complete fusion always occurred as judged from microscopic sections. So far, sixty palatal explants treated with cortisone have been followed in prolonged cultures without a single case of persistent cleft between the shelves.

The percentage of palates in which clefts were induced in vivo was approximately 35 per cent in our Yet all shelves cultivated in random population. vitro showed a tissue response to cortisone detectable as retardation of growth and fusion of the palatal processes. Despite this invariable response, none of the shelves failed to fuse in prolonged cultures. These results suggest that the end result of cortisone treatment in vivo, the palatal defect, is a summation of two factors: a direct effect of the hormone on the palatal tissue and the genetically determined developmental events of the head region. Thus the results obtained in this study can be well fitted into the hypothesis of Fraser.

Protein Synthesis in Tonic and Phasic Skeletal Muscles

LITTLE is known of the way in which physiological function influences protein metabolism in muscle. Knowledge in this area is essential if we are to understand the biochemical mechanisms through which use and disuse alter muscle size and functional capacity. The present studies were undertaken to see if the level of protein synthesis in different skeletal muscles varies systematically with

different types of physiological activity.

It has long been known1,2 that slowly contracting skeletal muscles are darker in colour than the phasic ones. The former perform continuous, tonic work and depend primarily on oxidative metabolism3 while the faster, pale muscles fatigue more easily, are less frequently active and rely primarily on glycolytic metabolism3. muscles are of an intermediate character, being composed of both dark and light fibres in varying proportions. Henneman et al.4 demonstrated that the dark fibres are innervated by neurones with thresholds lower than those innervating the pale fibres. As a result, these dark fibres are usually more active than the larger, pale ones, which are recruited only during greater muscular efforts. average amount of electrical activity in a muscle is thus related to the proportion of dark fibres. The present experiments demonstrate that the amount of protein synthesis in a muscle is determined by the proportion of dark fibres. We have compared the ability to concentrate a non-utilized amino-acid analogue, the amount of incorporation of ¹⁴C-leucine into sarcoplasmic and myofibrillar proteins, as well as the RNA contents of red and white

In order to study protein synthesis in muscles in the absence of growth, we used hypophysectomized rats (100-120 g, Charles River strain), 4 weeks after removal of the pituitary^{5,7}. Results similar to those presented here have also been obtained with muscles from normally

growing rats.

Christensen et al. showed that the amino-acid analogue, α-aminoisobutyric acid (AIB), although not metabolized, is transported into cells by the same membrane systems which transport natural amino-acids. The relative ability of cells to take up this analogue presumably reflects differences in the rates at which they utilize amino-acids. Table 1 shows that red muscles concentrate ¹⁴C-AIB to a greater extent than the pale ones. 3 μc. of ¹⁴C-AIB-1 (2·76 mc./mg) dissolved in 0·3 ml. of physiological saline was injected intravenously into unanaesthetized rats. The animals were killed 4 h later and the muscle was excised. Tissue water was estimated as the difference between the wet and dry weights of the muscles. The dried muscles were then dissolved and their ¹⁴C-AIB content was measured by liquid scintillation.

The values presented in Table 1 are the ratios of the concentration of AIB in various muscles to that in the plasma. No attempt was made to correct these values for differences in the extracellular space in the different muscles. The extracellular component is greater in dark muscles than in pale ones, and so the data in Table 1 are probably an underestimate of the actual differences in the

Table 1. UPTAKE OF 14C-AIB BY RED AND WHITE SKELETAL MUSCLES

	Distribution ratio	Proportion of dark fibres

Muscles are arranged according to average content of dark fibres, as measured by Streter and Woo?. Values given are the ratios of concentration of ¹⁴C-AIB in total muscle water to that in plasma 4 h after intravenous injection. Each is the mean ± S.E. of seven muscles.

ability of red and white muscles to concentrate AIB from the extracellular fluid.

Because amino-acids are not appreciably metabolized by muscles, the differences shown in Table 1 presumably reflect different rates of incorporation of amino-acids into Evidence in support of this conclusion is proteins. presented in Table 2, which compares the amount of ¹⁴C-leucine incorporated into sareoplasmic and myofibrillar proteins in various skeletal muscles. 3 μe. of ¹⁴C-leucine (1.89 mc./mg) was injected subcutaneously 24 h before the animals were killed. Samples (50 mg) of each muscle were then taken for analysis. The proteins in each fraction were isolated and their radioactivities were assayed as described previously7. The dark muscles incorporated more 14C into both soluble and fibrillar proteins (Table 2) than did the pale ones, and thus the 14C incorporation was greater in those muscles showing greater AIB uptake.

Table 2. Incorporation of Leucine-u-14c into proteins by Med and white skeletal muscles

Salubla fraction Muchbriller fraction

	Counts/min/mg	of fresh muscle
Diaphragm	4.4 ± 0.3	6-3±0-3
Soleus	3.7 ± 0.2	5-6 ± 0-2
Medial gastrocnemius	3.3 ± 0.2	5-3 ± 0-4
Plantaris	3.0 ± 0.1	4·8 ± 0·2
Extensor digitorium longus	3-0 ± 0-1	4-5±0-2
Lateral gastrocnemius	2.3 ± 0.2	3-7 ± 0-2

Values are the mean $\pm S.E.$ of at least seven observations. The involutional fraction includes some nuclear and stromal material, although at least 90 per cent of the radioactivity can be extracted as myofibrillar proteins.

To obtain further evidence for differences in protein synthetic activity, the RNA content of various muscles was also determined. Spectrophotometric analysis following reaction with orcinol was performed as originally described by Schmidt and Tannhauser¹⁰ but various suggestions of Monro and Fleck¹⁰ were incorporated. Soluble RNA prepared from yeast (Sigma Chemical Co., Type XI) was used as a standard. Red muscles have a greater content of RNA/mg than the white ones (Table 3). A similar observation was made by Margreth and Novello¹² although these workers compared muscles from different species which were growing at different rates.

Table 3. RNA CONTENT OF RED AND WHITE SKELETAL MUSCLESS

	μg KNA/mg muscle v
Soleus	7·1 ± 0·26
Medial gastrocnemius	5·8 ± 0·20
Diaphragm	5·6 ± 0·18
Plantaris	4.6 ± 0.14
Extensor digitorium longus	4.0 ± 0.18
Lateral gastrocnemius	90-0+8-8

Values are the mean $\pm S.E.$ of ten observations.

Qualitatively, the muscles with the highest RNA content are also those most active in AIB transport and aminoacid incorporation, although the exact order of the muscles in Tables 1, 2 and 3 is not identical. More than a qualitative agreement between these different approaches is not surprising, because each measures a different aspect of protein synthetic activity. Table 3 (KNA content) is, presumably, a reflexion of the amount of machinery for protein synthesis usually present in the muscles; Table 2 (14C-leucine incorporation) is, presumably, a measure of the amount of protein made in the various muscles over a period of 24 h; while Table 1 (14C-AIB) is an estimate of the extent of amino-acid uptake during a 4 h period when the animals are awake. Because the muscles of hypophysectomized animals remain constant in size, protein synthesis and protein degradation must be equally balanced. The present findings therefore also demonstrate that the amount of protein usually catabolized for every mg of muscle is greater in red muscles than in white ones. In other words, the average half lives of skeletal muscle proteins, both soluble and myofibrillar, vary in different muscles, and are smaller in the tonic muscles than in the phasic ones.

Greater protein catabolism may be a fundamental characteristic of the tonic muscles, such that greater protein synthesis is secondarily necessary for the cell to

Theoretically, the different maintain constant size. average rates of protein degradation could arise in two ways. On the one hand, certain proteins found only in the red muscles could be very short lived and therefore the average amount of protein catabolized at any time would appear greater in these muscles. On the other hand, the same proteins may turn over at different rates in the different muscles, being more labile when the muscles are used tonically than when used phasically. Measurement of turnover rates of specific proteins in different skeletal muscles would help one to decide between these alternatives.

Recently, Peterson¹² found by autoradiography that small motor neurones incorporate more amino-acids into proteins per unit volume than large ones do. This finding on spinal neurones is very similar to the results reported here. The small motor neurones and the tonic muscle fibres which they innervate are both used more frequently and seem more active in protein synthesis than the large nerve and muscle fibres4. Thus an association between physiological activity and amount of protein metabolism may be quite general. Additional studies (ref. 13 and my unpublished work) further demonstrate that the parameters of protein synthesis measured here can change rapidly in response to changes in functional demand.

I thank Dr H. M. Goodman for his guidance and support. This work was supported by a grant from the Milton Fund of Harvard University.

Inhibition of Egg Implantation and Induction of Abortion in Mice by Heterologous Immune Serum

IMMUNOLOGICAL reactions between mother and conceptus play an important part during pregnancy. It has, for example, been shown that placental size¹⁻³, foetal size⁴ and length of gestation4 can be influenced by the immunological relationship between mother and foetus. As early as implantation the mouse embryo is capable of expressing transplantation antigens and the mother can react to them^{5,*}. Mouse eggs which are genetically most dissimilar from the mother are more readily implanted. This is also true of the rat (personal communication from W. K. Silvers and D. Wilson). It has been suggested that immunological selection of eggs at implantation might be a contributory determinant of sex ratio8.

In view of the antigenicity of the embryo and the immunological competence of the mother it is not surprising that there have been many attempts to prevent

or to terminate pregnancy by specifically immunizing the mother against paternal transplantation antigens present in the foetus. Without exception all these measures have proved ineffective. Indeed, there is evidence which may be interpreted as suggesting that immunizing procedures of this sort increase fecundity rather than the converse.

The experiments described here were performed to investigate the effect on pregnancy of an immune serum raised in rabbits by intravenous injection of living mouse thymocytes by the method described by Levey and Medawar¹⁰. The serum was not absorbed and in addition to its antithymocyte immuno-suppressive activity it would contain a range of antibodies including haemagglutinins. Control serum was obtained from rabbits not previously injected with thymocytes. The serum was injected subcutaneously, 0.5 ml. in each injection.

The mice were from a heterogeneous colony. They were sexually mature and weighed 25-30 g. The appearance of the copulation plug was considered as day 0 of pregnancy. Egg implantation occurs on the fourth day.

In all the experiments equal numbers of mice were injected with control serum. Approximately 90 per cent of these mice delivered a normal litter 18 days after mating. This does not differ from the breeding performance of untreated stock mice, and so it was assumed that control serum in no way affected the normal course of pregnancy and the individual results will not be included.

The results (Table 1) show that the serum causes involution of the corpora lutea and the immediate termination of pregnancy. The action can be reversed by the simultaneous administration of progesterone (experiments 4a, 4b and 5). The mechanism of action of the serum in bringing about these changes in the corpora lutea cannot yet be explained. It is a short lived effect; mice will remate shortly after abortion induced by serum and carry the litter to term (experiment 4c).

Serum given soon after mating prevents egg implantation, even when exogenous progesterone has restored the sensitivity of the uterus to corn oil, an artificial deciduogenic stimulus (experiment 2). Finn¹³ considers that this stimulus can produce decidual reaction only when the hormonal status of the uterus will allow an egg to implant. Blastocysts taken from mice treated with serum fail to

implant when transplanted to the uterus of an untreated pseudopregnant foster mother (experiment 1b).

Although these results suggest that the serum impaired the viability of the eggs, further experiments showed that this was not so. Blastocysts from serum-treated mice will develop satisfactorily when transplanted to the testes of untreated hosts (experiment 1c). Furthermore, blastocysts taken from untreated donors will develop beneath the kidney capsule of mice treated with serum (experiment 3).

It seems then that neither the sensitivity of the uterus nor the viability of the egg is adversely affected by the treatment. Presumably the serum has interfered with the mechanism whereby the blastocyst initiates the decidual response, a sine qua non of implantation in the uterus but not in extra-uterine sites. Eggs transplanted from treated donors to the pseudopregnant uterus of nontreated hosts (experiment 1c) must be explained by a local action of the serum carried across on the surface of the egg. A similar argument has been used by Guttmann et al.14 to account for the prolonged survival of renal allografts in rats when only the donor had been treated with anti-lymphocytic serum.

The way in which the serum inhibits the induction of a decidual reaction by the egg is unknown. Its action may be non-specific; it may damage the uterine tissues or interfere with the hormones required for implantation. The findings are also consistent with the view that the serum has inhibited an immunological interaction between

blastocyst and uterus.

Tyler¹⁵ first postulated that "implantation itself may involve interactions that are of antigen-antibody type" The following recent findings may be interpreted as lending support for this idea. (a) The mouse egg expresses transplantation antigens. (b) There is selection of blastocysts of particular genotype at implantation in the mouse? (c) Antigen contained in the blastocoelic fluid of the rabbit blastocyst is also found in the uterine lumen and uterine stromal cells just before implantation16. (d) At implantation the antimesometrial uterine epithelium cells in the rat show a marked ability to transfer substances even of high molecular weight to the subepithelial space 17. (e) In the sub-epithelial space in the mouse there is an accumulation of lymphocytes and other white blood cells around the site of, and at the time of, egg implantation 18. (f) Only the blastocyst, not other objects similar in size, is able to induce a decidual reaction in the mouse¹⁹. This suggests that the reaction is induced by something more than the physical presence of the blastocyst. If implantation requires the recognition of antigens displayed by the egg, there is some evidence to suggest that they may be tissue specific20 and/or strain specific7.

Further work is needed using purified haemagglutinating and thymocyte antisera to determine the cause of these

Pharmacology of the Mechanism of Certain Effects of Reserpine in the Rat

TWENTY minutes after receiving large doses of reserpine (5 mg/kg, given intraperitoneally), rats develop a myohypertonic-hypokinetic-cataleptic state, showing generalized tremor, piloerection, diarrhoea, ptosis and cutaneous hyperalgesia. In such a state rats do not move, but allow themselves to be dragged by the tail. The ptosis is reversible during the first 40 min after its appearance and then irreversible (compare refs. 1 and 2). We have found that the symptoms remain unaltered for 24 h, and then gradually subside to a practically normal state after 48 h. When the forelimbs of the animal under the influence of reserpine were placed on the edge of a table, and the rat held by the tail, it remained still in this position, unlike normal animals which would climb quickly onto the table. Rats placed on the edge of an open cage on their abdomen behave similarly; they do not climb or jump down as normal rats would do. The animals treated with reserpine find it difficult to swim in water and do so in an oblique (or sloping) position, and they cannot get themselves out of the water bath. Normal rate swim quickly in a near horizontal position and get out of the water easily.

An identical state can be produced by injecting the rats intraperitoneally with large doses of serotonia or tryptamine (30 mg/kg). In the case of serotonin, however, such a state is observed only in a second phase. During the first phase (between 2 and 40 min after injection) rats show total flaccid paralysis with analgesia, but with the rest of the sensory system apparently undisturbed. The second phase after injection of serotonin (after 40 min) is identical with the state observed after an injection of reserpine. The serotonin effect disappears gradually after 2 h. When tryptamine is given there is only one phase of reaction; the animals show the same symptoms which reserpine produces immediately (2 min) after injection and these effects last for 1 h.

Doses of 2 mg/kg of adrenergic agents (adrenaline and noradrenaline) produce a different depressive state, with myohypotonia, analgesia and semiptosis.

Pharmacological assays have shown us that there is more than a casual similarity between the effects of reserpine and those of serotonin and tryptamine. We can summarize the results of our experiments as follows. (a) The antiserotoninic drug methysergide injected intraperitoneally in a dose of 5 mg/kg 50 min before the administration of reserpine postponed the appearance of its effects by 45 min. A second dose of methysergide if given 10 min after reserpine completely blocked the effects of the reserpine. The effects of serotonin and tryptamine were inhibited by one dose of methysergide injected 50 min before the administration of these drugs, and the animals remained in a completely normal state. LSD and BOL (bromolysergic acid diethylamide) (2 mg/kg) only delayed the appearance of the effects of reserpine for 40-60 min. None of these drugs depress catecholamine.

(b) Adrenergic blocking agents (10 mg/kg of phentolamine, 5 mg/kg of dihydroergotamine and 1 mg/kg of propanolol) administered in the same way did not affect the symptoms produced by reservine and serotonin. They also had no effect on catecholamine depression.

(c) Centrally active anticholinergic drugs (atropine and benactyzine, in doses of up to 30 mg/kg) showed no effect on the symptoms produced by reserpine and serotonin, nor did they affect catecholamine depression.

(d) The antihistamine drugs ('Phenergan' and 'Benadryl', in doses of up to 30 mg/kg) had a sedative effect, but were without effect on the symptoms produced by

reserpine, serotonin or catecholamines.

(e) The inhibitors of monoamine oxidase (iproniazid in a dose of 100 mg/kg, nialamide in a dose of 50 mg/kg or tranyleypromine in a dose of 30 mg/kg) delayed the second phase of the effects of serotonin and reserpine, but did not inhibit them. Iproniazid injected 24 h before reserpine and serotonin delayed their effects for 4 h; nialamide injected 24 h before, and tranycypromine injected 1 h before, delayed the appearance of the effects for 35 min. The serotonin paralysis of the first phase was markedly reduced by these drugs; the flaccidity was less pronounced and the animals tried to move with some No effect on catecholamine depression was success.

(f) Injection of 500 mg/kg of dopa 20 min earlier postponed the effect of reserpine by 4 h, inhibiting the action of serotonin and tryptamine completely; 200 mg/kg had no effect on the effects of reserpine, but blocked the tryptamine symptoms and the second phase of the

serotonin effects.

(g) Clinical antidepressive drugs, such as imipramine, desmethylimipramine, amitryptiline and nortryptiline, in doses of up to 50 mg/kg similarly retarded the appearance of the effects of serotonin and reserpine without blocking them. Catecholamine depression was not modified in any way by these drugs.

(h) Antiparkinson drugs ('Tremaril', 'Diparcol' and 'Parsidol'), in doses of up to 30 mg/kg, completely inhibited the effects of reserpine and serotonin. 'Aturban' had no effect. None of these drugs had any action on the

symptoms produced by catecholamines.

(i) Phenylethylamine and methylamphetamine, in a dose of 10 mg/kg, inhibited the effects of reserpine and serotonin and those of catecholamines (compare

ref. 3).

It is interesting that dopa postponed the effects of reserpine and inhibited those of serotonin and tryptamine, but it is difficult to see this as evidence that a depletion of catecholamines is the cause of the effects of reserpine, unless the same mechanism also applies to the effects of serotonin and tryptamine. The situation is similar with regard to the temporary blocking action of inhibitors of monoamine oxidase.

The inhibition of the effects of both reserpine and serotonin by the antiserotoninic drug methysergide argues in favour of the hypothesis of Brodie and Shore4 that reserpine acts by releasing serotonin, at least as far as the Nevertheless, effects observed by us are concerned. tryptaminic mechanisms would also fit in with our results. There are further implications in the complete inhibition of the effects of reserpine and serotonin by antiparkinson drugs while other central anticholinergic drugs were inactive in this respect.

Neuro-interstitial Junction in a Gastropod, Glossodoris

On the basis of ultrastructural observations, we have suggested a unified "glio-interstitial" cell-system in the Mediterranean sea-slug Glossodoris1. This system includes the glial cells described in the central nervous system of several gastropods²⁻³ and the "interstitial cells" associated with the peripheral nervous system. The later non-neuronal elements resemble the "interstitial cells of Cajal" in the peripheral nervous system of vertebrates4 in their relationship with nerve plexuses and smooth muscle fibres, in their morphology and in their staining properties (ref. 5 and my unpublished results). A special type of junction between nerve fibres and interstitial cells has been found in an electron microscope study of the foot of Glossodoris tricolor (Cantraine).

This junction is formed by an apposition of membranes with morphological polarization and differentiation, as in a regular nervous synapse. Fig. 1 shows nerve fibres lying in close contact with the interstitial cell. In two places the membranes are thickened and densely stained (differentiation) and the intercellular cleft is reduced to 120 A. The nervous side of the contact shows a striking accumulation of vesicles (polarization) which are the same size as "synaptic vesicles" (300-800 Å), but some of them have an electron-dense core (200 Å) separated from the outer membrane by a clear space. This second type is similar to the vesicles in the vertebrate nervous system6 which are thought to contain catecholamines.

Arrows indicate synaptoid contacts. c, Collagen; g, interstitial granules; n, neurite; nu, nucleus of the interstitial cell.

Both the differentiation and the polarization suggest that these contacts represent the site of special exchange between the nerve fibre and the interstitial element, apparently directed from the nerve process toward the interstitial cell. The structure of the neuro-interstitial junction is similar to that of the neuromuscular junction

McGeer, P. L., J. Neuropsychol., 4, 247 (1963).

in Glossodoris (my unpublished results) which suggests that the interstitial cell itself may be an effector. We have not yet seen a similar synaptoid association of nerve fibres with glial elements in the central nervous system of Glossodoris, but a parallel description of a neuro-interstitial junction in man has been published?, and there have been indications of neuro-ependymal connexions in other vertebrates*,

Polarized and differentiated contact may permit neuronal input to the glio-interstitial system. There are also three possible outputs from the system: (1) a localized action on muscle, suggested by the close contact between interstitial elements and muscle fibres (unpublished results); (2) a direct effect on neurones, where the relationship of interstitial cells with peripheral neurones parallels that of glial cells with central nervous elements, which is most conspicuously developed in the trophospongium; (3) a diffuse humoral influence on the surrounding tissues, suggested by electron micrographs which show the extrusion of granules at random points on the interstitial cell surface.

Further physiological information is necessary to establish the function of the glio-interstitial system, but the morphological data suggest that it plays an active part in nervous and neuromuscular physiology.

State-dependent Learning produced with Steroids

THERE have been three sets of discoveries on the effects of chemical substances on behaviour. First, it has been shown that chemical agents, especially endocrine hormones, can predispose animals to display particular species-typical ("instinctive") actions such as mating, nest building and care of the young1,2. Second, it has been found that generalized stimulating, anti-depressant, tranquillizing or psychotomimetic effects on behaviour can be produced by certain chemical agents sometimes referred to as "psychotropic" drugs3. Third, it has been established that a response learned in a given chemical state is more likely to occur when the subject is in that particular state than when he is not; this phenomenon is called state-dependent learning or "drug dissociation". Only the third discovery indicates that it may be possible to obtain specific or discriminative chemical control over any chosen response through learning. It provides a means for understanding how the specific idiosyncratic response patterns comprising "personality" could come under chemical control.

Evidence that drugs can be made to have discriminative control over learned responses was first provided by Girden's experiments with raw curare⁵⁻⁷. His work has recently been corroborated and extended by other investigators using different drugs and responses 8-13. In a typical experiment, animals are rewarded for making one of two alternative responses (for example, turning right in a T-maze) while in one drug state, and for making the

other response (turning left) while in a second—usually a non-drug-state. They learn to go to the correct side on every trial.

Drugs used in recent experiments have included a variety of depressant and hypnotic agents such as barbiturates, ethyl alcohol, chlorpromazine and atropine sulphate, but state-dependent learning has not yet been demonstrated with chemicals usually produced in the

We have investigated whether steroids known to affect the central nervous system can be used as a basis of statedependent learning. Progesterone was chosen because it has hypnotic properties as have many drugs known to be capable of producing such learning14. Hypnosis is induced only with high doses of progesterone, so we started the investigation with hydroxydione sodium ('Viadril'), a synthetic compound with strong hypnotic properties15 which has a close chemical resemblance to progesterone. experiment with 'Viadril' was carried out first with male rats. When we had shown that state-dependent learning could be obtained with this compound, we changed to ovariectomized female rats for the progesterone study.

Two groups of adult hooded rats, fifteen males and eleven ovariectomized females, were trained to escape from a 0.9-1.6 m.amp scrambled electric shock in a T-maze. Each arm of the maze was 24 in. long, 8 in. wide and 8 in. high. Uniform light was provided through a translucent roof, which eliminated extra-maze visual enes. The animals were observed through one-way vision glass in the side-walls of the maze. All the floor could be electrified but the last 12 in. of the right or left arm of the T could be made "safe" by disconnecting the relevant circuit.

On each trial the floor of the maze was electrified and the rat was dropped into the starting area, facing away from the alley. It was allowed to run freely until it reached the safe goal-box. Each rat was trained to run to one arm of the T while in a "drug state" (DS), and to the opposite arm while in a "non-drug state" (NDS). In each group some rats were trained to go left in DS and right in NDS, while others were trained to go right in DS and left in NDS. Both the chemical state and the direction of turn required alternated on successive days: animals from each group were given DS trials on days 1, 3, 5, etc., while others were given DS trials on days 2, 4, 6, etc. An injection of 0.5 ml. of isotonic saline constituted NDS. The dose of 'Viadril' given to each male animal (Group I) on DS days was $25~\mathrm{mg/kg}$ ($10~\mathrm{mg/ml}$, distilled water). For female rats (Group II) the dose of progesterone, chosen on the basis of prior tests, was 100 mg/kg (100 mg/ml. in a 2 per cent solution of carboxymethyl cellulose). All injections were given intraperitoneally 15-30 min before the test. Drugged animals were tested as soon as signs of sedation (ataxia, drowsiness) were evident; occasionally, a supplementary injection was given because signs of sedation did not appear after the first injection.

The daily training of each animal consisted of five or ten trials about 2 min apart. The first arm of the maze entered by the rat was recorded. If the entire body of the animal moved into an arm from the choice area, an "entry" was scored. The direction of turn made by the animal on the first trial of each daily session indicated the degree of control the chemical states (DS and NDS) had over response choice. The correct first trial responses for two sessions (one DS day and one NDS day) are plotted as percentages in Fig. 1. (Almost all choices made after the first trial were correct.) The learning curves represent the combined results of all animals tested. In each group there was at least one animal which made no more than three incorrect choices in all trials, but there were two animals in each group whose first trial performance indicated no state-dependent learning. Animals given saline injections daily and trained to change direction on alternate days performed in a way which could be expected

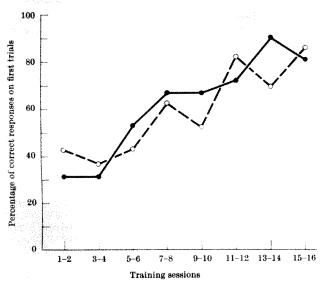

Fig. 1. Percentage of correct choices made by groups of rats on the first trials of two successive sessions, one after drug treatment and one after saline, \(\int ---\), Group I ('Viadril' versus saline), fifteen males; \(\int ---\), Group II (progesterone versus saline), eleven ovariectomized females.

by chance, indicating that the animals in the two experimental groups learned to make the correct choice on the basis of the drug state alone. This demonstration by no means proves that substances such as progesterone usually determine idiosyncratic response tendencies, or changes in response with variations in their blood con-The amount of progesterone used in this centrations. study greatly exceeds normal blood levels. Changes in complex behaviour patterns are sometimes closely associated with changes in blood chemistry and these changes are often idiosyncratic, being variable from individual to Some responses (for example, behaviour individual. during premenstrual depression) are persistent as long as certain humoral states obtain, but they are quickly disrupted by changes in those states. The persistence of responses can occur in spite of changes in the external environment, whereas their elimination can occur even when the environment appears to be constant. We should perhaps consider the possibility that through learning the responses may have become tied to certain chemical

Control of Muscular Contractions by Spinal Neurones in Amphioxus (Branchiostoma lanceolatum)

A VARIETY of electrical events can be demonstrated in the nerve cord and myotomes of amphioxus by conventional electrophysiological methods, following electrical, mechanical or photic stimulation. Fine silver wire electrodes (20–30 μ) or tungsten micro-electrodes (2·0–0·5 μ) proved more satisfactory than glass capillaries. Recordings were made from the intact animal, from preparations stripped off muscles and from isolated nerve cords. Further details of the experimental procedure will be

published elsewhere.

Afferent volleys seem to be localized, and at recording points distant from the stimulus only interneurones respond. Photoreceptor potentials were only detectable by microelectrode penetrations and do not differ greatly from interneurone signals. Both photic and mechanical stimuli result in the appearance at different levels in the cord of brief trains of between one and five impulses the spacing of which increases from 100 to 480 msec in a typical series (Fig. 1A). The duration of each impulse is about 3.5 msec. The magnitude is constant for any electrode position and is always relatively large (over 10 µV). When two recording points on the nerve cord were employed to pick up trains of such potentials the decline in frequency was more pronounced at the electrodes furthest from the stimulus point, suggesting the involvement of a series of elements rather than continuous axons. These observations suggest that the elements involved are the large Rhode interneurones described by Bone¹ and others. The maximum rate of conduction in these fibres is between 1.5 and 2.0 m/sec compared with 0·3-1·0 m/sec in the smaller elements. Following the Rhode cell potentials in a response series are signals varying a good deal in number, magnitude and spacing. They usually seem to form compound potentials (Fig. 1B). Their total amplitude almost always exceeds that of Rhode cell impulses, but the form that they take varies considerably with the position of the electrodes. A single Rhode cell potential precedes one to five potentials of this kind, the first following the Rhode impulse by 50-100 msec. Given a sufficiently high level of stimulation several muscular waves pass down the animal and the activity of Rhode and post-Rhode elements is repeated at 2-3 c/s. Other low value signals also appear and are perhaps involved in this maintained activity. disappear as the swimming movements slow down. The compound nature and localization of the post-Rhode cell activity point to its origin in the somatic motor cell clusters shown by anatomists.

Recordings from the myotomes have so far given rather variable results, but in ideal conditions brief bursts of potentials can be seen to accompany muscular twitches

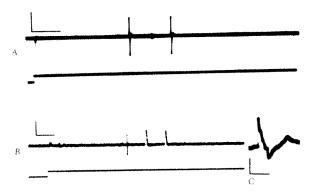

Fig. 1. A and B, Responses from the nerve cord (upper traces) to a beam of light directed against the flank (step on lower traces). C, A compound potential similar to that shown in B. Vertical scale: A, 15 μ V; B, 15 μ V; C, 10 μ V. Horizontal scale: A, 0-2 sec; B, 0-1 sec; C, 50 msec.

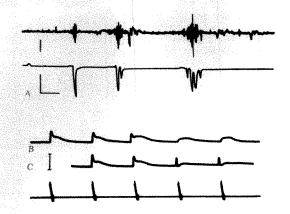

Fig. 2. A, Electrical record (upper trace) and mechanical responses (lower trace) from the thirty-fifth myotome, following mechanical stimulation of the head. B and C, Mechanical response from a myotome resulting from electrical stimulation within the adjacent nerve cord at 1 c/s. B illustrates the effect of altering the position of the electrode, and C the result of lengthening the duration of the stimulus pulse from 4 to 9 msec. Vertical scale: A, upper trace 20 μ V, lower trace 3 g; B and C, 2 g. Horizontal scale: A, 1.0 sec. In B the scale is given by the stimulus marker on the lowest trace.

(Fig. 2A). These often occur against a background of larger single potentials (100 μ V) repeated at 1–2/sec. The latter may be tonic in nature but further evidence is necessary.

Direct electrical stimulations of the muscle fibres reveal a rapidly fatiguing system the frequency discrimination of which declines rapidly above 10 c/s, a fused contraction increasing as repetitive twitches decline. The dual nature of the contractual response is much more clearly demonstrated by stimulation of the myotomes from sites within the nerve cord, when a fast and a slow component can be separated by electrode localization (Fig. 2B) or duration of stimulus (Fig. 2C). This is in accord with the separation of fast and slow muscle contacts with the nerve cord demonstrated anatomically by Flood².

The general impression of the nature of spinal neurone activity in amphioxus is of a system usually working at a low level, but capable of being driven into a state of much higher and more continuous activity by stimulation. The rate of spontaneous activity is less than two impulses, see at 20° C in the quiescent animal. When few neurones are active, responses decay rapidly. A sufficiently high level of stimulation results in many more neurones becoming active and the animal is able to swim rapidly and accurately at speeds up to 40 cm/sec.

Effect of Promethazine Hydrochloride on the Release of Gastrin in the Dog

Antihistaminic drugs do not inhibit acid secretion stimulated by histamine or insulin in the dog, but given intravenously they do suppress the secretory response to endogenous gastrin^{1,2}. Payne et al.², after testing several antihistamines, suggested that the specific pharmacological mechanism of this phenomenon was their atropine like (anticholinergic) effect. It is, however, difficult to

reconcile this explanation with the fact that t phase of acid secretion, stimulated by insul glycaemia, was apparently unaffected by t histaminics¹.

Atropine, used systemically^{2,3,5,7} or applied to to the antrum, suppresses the secretory resendogenous gastrin, and has been suggested to this effect by blocking the release of gastrin froundetermined cell of origin. We have thought gastrin mechanism is suppressed differently by and by promethazine.

The availability of pure gastrin and the "gas polypeptides has made possible further investithis problem. The present experiments confered of promethazine with that of atropine on tory responses to both endogenous and exogenous

Intravenous promethazine (1 mg/kg) has be to diminish markedly the acid secretion induced stimulation with liver suspension. We have no out similar experiments to show that endogenor released by topical stimulation of the antiacetylcholine chloride is also inhibited by pror A dog, prepared with denervated antral as pouches and also a gastrostomy, was fasted Then acid secretion was stimulated by perfus antral pouch with a 0.5 per cent solution of acc at a rate of 0.43 ml./min and at a pressure of water. Gastric juice was collected at 10 min from both the fundic pouch and the main storms the rate of secretion reached a plateau, a six venous injection of promethazine (1 mg/kg) during 3-4 min and collections were continu acidity was titrated to the Töpfer's reagent (pH 3.5). Three experiments, comparing ac from the hour before and the hour after the is promethazine, were carried out with this pr The promethazine caused a 72-91 per cent in acid secretion presumably by either (a) prevent release, (b) blocking the action of gastrin after or (c) both of these mechanisms.

In order to elucidate this action of protwelve further experiments were carried or dogs with gastrostomy cannulas (and in ordenervated fundic pouch as well). Contine venous infusions of gastrin pentapeptide* (1 p. 1.5-2.5 h resulted in a plateau of acid outputively similar to that produced by endogens released by the topical application of acetylch was followed by a single slow intravenous i promethazine (1 mg/kg). There was no signiff of promethazine on the exogenous "gastrin" secretion (Table 1).

Table 1. EFFECTS OF PROMETHAZINE AND ATROPINE ON SECLATED BY GASTRIN PENTAPEPTIDE

	Stomach	
Atropine	$91.7 \pm 1.4 (10)$	57- <u>%</u>
	P < 0.001	F
Promethazine	$6.8 \pm 9.1 (12)$	5.
	P > 0.1	.0

Values given are means of percentage inhibition ± standa; bers in parentheses are the number of experiments carried of P represent the probability that inhibition observed was risgnificant compared with no inhibition.

In similar experiments using intravenous at dosage of 0.02 mg/kg (said to have equivibrilarly cholinergic potency to promethazine in a dose (ref. 2), there was marked inhibition of the "gastrin" (Table 1). The range of reduction of the was 82-96 per cent in the stomach and 50 in the denervated fundic pouch.

* Because of its availability, gastrin pentapeptide (N-i-but B-alanyl-tryptophanyl-methionyl-aspartyl-phenylalanine am was used. It possesses secretory effects qualitatively similar tatively less potent than gastrin. Imperial Chemical Indus England, and Ayerst Laboratories, New York, NY, supplied t nism. Atropine blocks the effects of and exogenous gastrin, while proly endogenous gastrin. In other mine seems to work by inhibiting 1 from its cell of origin, but, once its secretory effect is unaltered by

ling Capacity related f Histamine

ve indicated that an increase in the ımine can be regarded as an important esensitization. In these experiments, bound histamine was found in the er repeated injections of histamine. teresting to look for a relationship of histamine to the tissues and their s substance.

carried out with male albino mice An intraperitoneal infusion of histacarbon-14 was given over 24 h. Fine long enough to allow the mouse access s well as freedom of movement in the nto the peritoneal cavity. Histamine) and 100 µg/g of mouse (containing nistamine) were prepared in 1.3 ml. of volume infused over 24 h by means of a motor. The mice were then kept conditions to allow unbound histamine urine and faeces. Forty-eight hours infusion, each mouse was homogenized with 200 ml. of 10 per cent trichlorod. of histamine-histidine carrier (conhistamine dihydrochloric acid and 40 drochloride/ml.). Labelled histamine ording to the method of Waton2. The of untreated mice was measured ribed by Parratt and West³. Briefly, rogenized in 10 per cent trichloroacetic o stand for not less than 24 h. The extract was filtered, the excess acid nd the solution assayed on the isolated pig ileum. Specificity for histamine the mepyramine test⁴. All values of

the base. the mice during the infusion did not ed by the histamine, but a toxic effect pecause the LD_{50} of histamine given to illy, according to Angelakos and Loews.

histamine found 48 h after the end of the infusion are given in Table 1. These show that for the smaller doses $(0.1, 1.0 \text{ and } 10 \,\mu\text{g/g} \text{ of mouse})$ the percentage of histamine taken up in relation to the histamine supplied is similar in each case. For the larger dose (100 µg/g mouse) the value obtained is approximately seven times greater.

Table 1

No. of mice used	¹⁴ C-Hist- amine infused (dose/g of mouse/24 h)	¹⁴ C-Histamine bound, values/g of mouse with standard error of the mean	Percentage of histamine taken up in relation to histamine supplied	Percentage of histamine taken up in relation to the original histamine content $(9.8 \ \mu g/g)$
13	0·1 μg	0.033 ng ±0.002	0.033	3.4×10^{-4}
12	1·0 μg	0.38 ng ±0.05	0.038	3.9×10^{-3}
9	10 μg	3.5 ng ±0.38	0.035	3.6×10^{-2}
13	100 μg	258 ng ±58	0.258	2.6

In order to compare the amounts of bound histamine with histamine already present in the mouse, the histamine content of untreated mice was determined. The mean value for twelve mice was $9.8~\mu g/g$ of mouse with a standard error of the mean of $0.6~\mu g/g$. The uptake of histamine in each dose was expressed as a percentage of the original histamine content of the mice (Table 1).

These experiments do not indicate in which tissue of the mouse the histamine is bound. According to Beaumariage⁶, the skin of the mouse contains a large amount of histamine. Schayer, has shown that when 14C-histidine was injected into the mouse, histamine was formed and bound largely in the skin. Binding therefore probably

took place chiefly in the skin. The present results demonstrate that the binding of histamine is related to the supply of histamine. For a wide range of doses (0·1-10 µg of histamine/g) this relationship was consistent. When the dose of histamine was greater than the content of histamine already present in the mouse $(9.8~\mu g/g)$ this relationship changed, and the percentage of bound histamine increased. These results indicate that new histamine binding sites were formed after stimulation by the increased supply of histamine. If there was only a limited number of binding sites available, the percentage of bound histamine would decrease

however, do not support such an assumption. The data for histamine binding agree with earlier results¹. In these experiments, $10~\mu g$ of ¹⁴C-histamine/g of mouse was injected daily over 28 days. Three days after the end of the treatment, 109 ng of histamine/g of mouse was found; this value of daily histamine uptake (3.5 ng/g) was similar to that now obtained by the 24 h infusion of 10 µg of 14C-histamine/g of mouse.

as more histamine was administered.

Thus the provision of new histamine binding sites where the body can store histamine in a non-toxic, bound form may be regarded as an important factor in the mechanism of histamine desensitization.

This investigation was supported by a Nato-Forschungsstipendium. I thank Dr N. G. Waton for the facilities in the Department of Pharmacology, University of Strathelyde, Glasgow.

IMMUNOLOGY

Density Distribution Analysis of Lymphocyte Populations

DESPITE their suspected heterogeneity in origin, life span and precise function, lymphocytes are usually considered to be a single group because of the rather negative morphological criteria available. One morphological division of lymphocytes into immature (large and medium) and mature (small) cells is physiologically relevant, because the larger cells represent a population which synthesizes DNA and which divides, while the smaller cells are not usually engaged in DNA synthesis. Morphological criteria are as yet, however, inadequate to make possible identification of the classes of lymphocytes which are now studied by such functional tests as the ability to respond to antigen and to produce a colony of cells which form antibody, the ability to produce various classes of antibody or the ability to initiate a graft-versus-host reaction. This communication suggests equilibrium density gradient centrifugation as a technique which may prove valuable, not only in defining lymphocyte classes, but also in separating them from each other.

The procedure for separating lymphocytes on the basis of fine differences in their buoyant density is given in detail elsewhere1. The procedure reduces the effects of cell-to-cell interaction and maintains cells close to their original volume and density. Briefly, 107-109 lymphocytes are dispersed in a linear gradient of bovine plasma albumin (14-28 per cent w/w) in balanced salt solution at pH 5.1. To bring the cells to the position of their buoyant density, the tube is centrifuged at 3,700g for 45 min in the swingout head of a refrigerated centrifuge. About thirty fractions are collected by upward displacement of the gradient out of the top of the tube. After density determinations on each fraction have been made, the cells are recovered and their number, size/range distribution, morphological type and biological activity are accurately determined. From these data, a density distribution profile for each cell type can be computed and all results expressed in this form (cells/density increment

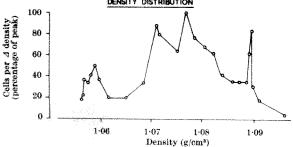

Fig. 1. Volume and density distribution curves for rat thymus cells. Both analyses were performed on the same preparation of 8 week old male Wistar rat thymus cells. The volume distribution was obtained with a model B Coulter cell counter equipped with a model J particle size distribution analyser.

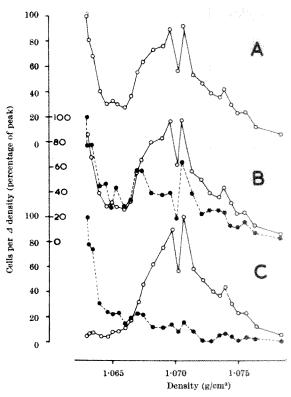

Fig. 2. Density distribution of cells of different morphological of and of different sizes. All curves are from a single run on 8 wes male rat thymus cells. On each density fraction, total cell counts az range distributions were performed using a model B Coulter cell counts and smears were prepared and stained with Giemsa for assessm morphological categories. From these data the density distribut the following types of cells was calculated. A, All cells; B, lymphocytes (\(\cdots --- \)) and medium and large lymphocytes (\(\cdots --- \)) as defined by morphological criteria; C, cells of volume 102-3 (\(\cdots --- \)), and of volume 325-342 \(\theta^2 \) (\(\cdots --- \)).

against density). The overall cell recovery is about cent and recovery of biological activity in a wide * of tests is in the range 60-90 per cent. The positive peak of cells is reproducible to ±0.0003 g/cm3 sta deviation, or to about one quarter of a fraction.

The method was originally designed to separate medium and small lymphocytes from each other. E the density of the cell should reflect the ratio between dense nucleus and lighter cytoplasm, small cells, the nucleus predominates, should be denser than large Instead of a simple separation by size alone, he lymphocytes from the thymus, lymph nodes, to duct lymph, blood and spleen all gave a much complex pattern composed of many discreet per shoulders. Fig. 1 shows the contrasts in the distr of size and range of rat thymus cells with the dens tribution of the same preparation. Further resolu this pattern with shallow gradients covering only a density range has revealed the presence of furth defined density populations.

Some indication of the nature of cells in various of the gradient is given in Fig. 2. Here the dense tributions of cells of a given morphological class, precisely defined volume, are plotted independe each other. As predicted, the upper regions of the are enriched for larger cells, the lower regions for cells. Some types of small lymphocytes, however the lighter zones and some types of larger cells in the Each morphological or size category separated into a series of density peaks. Such a tion may reflect the presence of several indelymphocyte populations, each with its own salarge, medium and small cells. Alternatively, reflect a series of definite metabolic stages through any one lymphocyte may pass in its development

This separation procedure has been applied to cells forming 19S haemolytic antibody directed against sheep red cells, as assayed by the Jerne plaque technique². In this case it is already known that a wide variety of cells may produce antibody, ranging from cells which might be classed as small lymphocytes, through large, dividing cells to the classical plasma cell^{3,4}. A typical density distribution pattern for tissue cells which form antibody is given in Fig. 3, the data in which were obtained with rat spleen 3 days after stimulation with antigen. pattern shows marked heterogeneity, with several distinct peaks which could be resolved more clearly with gradients

covering only a narrow density range.

To determine which part of the curve represented 'Vinblastine' was dividing cells, the mitotic inhibitor administered to the animal 5 h before analysis was made of density distribution. Because the drug did not seem to inactivate the cells which form antibody, it should arrest or cause a build-up of cells in the process of division and a relative depletion of product cells, compared with the untreated control. Fig. 3 shows that 'Vinblastine' caused a build-up of cells in certain regions and marked depletion in others. In general terms it seems that dividing cells are concentrated in the lighter regions of the gradient, and product cells in the denser regions.

The antibody forming cells circulating in the blood and thoracic duct give a quite different density distribution pattern from that of fixed tissue cells. This is in accordance with electron microscopic studies showing differences between fixed and circulating antibody forming cells3,5. An example is shown in Fig. 4. There is clearly a restriction

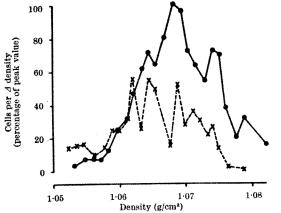

Fig. 3. Density distribution from rat spleen of haemolytic cells which form antibody. The analysis was performed 3 days after intravenous injection of a 9 week old male Wistar rat with 10° sheep crythrocytes. A separate animal was, in addition, injected intraperitoneally with 4 mg Vinblastine', 5 h (approximately one doubling time) before analysis. The areas under the two curves represent the relative numbers of antibody producing cells/spleen.

———, Control; × - - ×, treated with 'Vinblastine'.

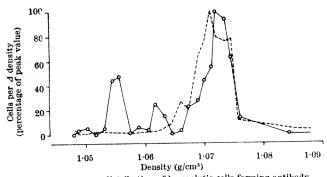

Fig. 4. The density distribution of haemolytic cells forming antibody, from the thoracic duct of a rat. A 9 week old male Wistar rat was injected with 10° sheep erythrocytes, half intravenously and half intraperitoneally, and cannulated 4 days later to collect lymphocytes from the thoracic duct. The analysis is on a 3 h collection of cells 4.5 days after antigenic stimulation. O. Antibody forming cells; . . . , total cells.

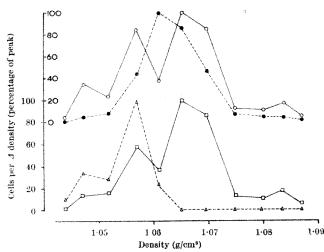

Fig. 5. Density distribution of graft-versus-host activity. The buffy-coat fraction from the blood of a single adult fowl was separated on the gradient and fractions assayed for pock forming ability on chick embryo chorioallantoic membrane, for total cell number using the model B Coulter cell counter and for morphological type using smeared and stained preparations. on the range of cells which produce antibody that enter the circulation. Some of the peaks of active cells are well separated from the bulk of the lymphocytes and up to

100-fold purification may be obtained.

Another application of the technique was to determine the nature of cells from chick blood which are capable of initiating a graft-versus-host reaction6, visualized as the formation of pocks on the chorioallantoic membrane of chick embryo7. This approach was prompted by the controversy over whether large or small lymphocytes were the effector cells in this system. Fig. 5 compares the overall density distribution of lymphocytes with the distribution of graft-versus-host activity. The activity would seem to reside in a small sub-population, distinct from the bulk of the lymphocytes. Activity cannot be attributed either to the total population of large, or to the total population of small, lymphocytes. The curves suggest that the bulk of the active cells have the morphological appearance of small lymphocytes, although a small proportion may be of the large lymphocyte type.

The general conclusion is that lymphocytes from many sources are composed not of a continuum of cell types but of a series of discreet populations, separable by fine differences in density. The possibility of artefacts is very real in such a sensitive procedure, but the control experiments we have presented elsewhere make it unlikely that artefacts significantly contribute to the overall density distribution profile. This view is supported by the differences in biological activity presented here and in the communication by Haskill⁸. It seems more likely that the density distribution profile reflects the existence of separate functional categories, and of discreet metabolic states or differentiation stages. The technique should provide a precise and objective means of studying in fine detail the immunological function of lymphocytes

Density Distribution Analysis of Antigen Sensitive Cells in the Rat

When lymphoid cells from spleen, lymph nodes or thoracic duct lymph are transferred together with sheep red cells to heavily irradiated recipients, an immune response occurs, the magnitude of which is related to the number of lymphoid cells injected1-3. Although Playfair1 and Kennedy² have described quantitative methods for determining the number of cells which are sensitive to antigens in such an inoculum, very little is known about the nature of these cells. The indications are that they are only slowly dividing or that most of them are in a resting state in the non-immunized animal4. Morphological evidence has been presented which tends to implicate small lymphocytes as cells which are sensitive to antigen. but the data are, as yet, unconvincing 5,6. The purpose of this work has been to use a different approach in characterizing these cells. The technique is that of sedimentation to equilibrium in density gradients of bovine serum albumin 7,8

A high resolution quantitative analysis of the density profile of cells sensitive to antigen was not routinely feasible using the assay methods of Playfair and Kennedy because of the large number of recipients needed. Two alternative methods have therefore been considered in this report. Syeklocha et al.4 have utilized the total number of antibody forming cells for the recipient spleen (defined by the Jerne plaque assay)9 as an index of the number of antigen sensitive cells in the donor inoculum. Albright et al. 10 have demonstrated a relationship between the number of injected spleen cells and the resulting antibody titre. Because the coefficient of variation in haemolysin titre from recipient to recipient is much less (12 per cent) than that observed for total plaque forming cells in the spleen (68 per cent), the mean haemolysin

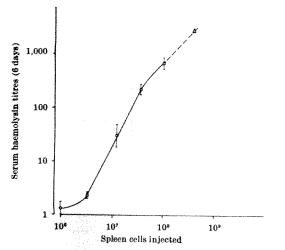

Fig. 1. Relationship between serum haemolysin titres taken on the sixth day and the number of spleen cells injected into irradiated recipients. All recipients received a dose of 850 rads of X-irradiation and 2×10° sheep red cells. The broken line extends to the maximum mean titre obtainable in non-irradiated animals. The mean variation in titre is indicated at each spleen cell concentration.

titre in recipients receiving various fractions of spleen cells has been used as a semi-quantitative assay for the measurement of cells which are sensitive to antigens. In every experiment, the total numbers of cells which form plaques have been determined and in all cases the agreement between the two methods of assay has been satis-

Spleen cells from male Lewis rats (9-10 weeks old) were injected together with 2×10° sheep red blood cells into male recipients (6-9 weeks old) which had received a dose of 750-850 rads of X-irradiation. The injections were carried out within 4 h of irradiation and the recipients were killed 6 days later to allow determination of haemolysin titres and total plaque forming cells in the spleen. In order to determine the profiles of cells which are sensitive to antigen, spleen cells were separated into ten to twenty-two fractions by equilibrium sedimentation in gradients of bovine serum albumin, before being injected into irradiated recipients.

The usual relationships between the number of injected spleen cells and the antibody titre was obtained as shown in Fig. 1. In order to calculate the relative number of cells sensitive to antigen in each density fraction, the mean haemolysin titre in each group of recipients was determined. Using this mean titre and the relationship between titre and unfractionated spleen cells (Fig. 1), the equivalent number of unfractionated spleen cells in each density fraction has been calculated. This number has been used in the determination of the density distribution profile of antigen sensitive cells. Recovery of biological activity has also been calculated from the equivalent numbers of spleen cells obtained from all fractions.

A typical profile for normal Lewis rats is shown in Fig. 2C. At least six different peaks of cells which are sensitive to antigen were observed. Although these same six components have always been observed, the relative importance of some of them has varied greatly from experiment to experiment. A possible reason for this variation will be discussed later. Recovery of biological activity in this type of experiment has been found to be 80-100 per cent.

In order to determine whether any of these peaks represented real differences in the biological properties of cells sensitive to antigens, the specific effect of antigenic stimulation was investigated. Because RNA and DNA synthesis are known to occur11 shortly after antigenic stimulation, it was expected that pronounced changes in the density profile of antigen sensitive cells would be observed on stimulation. The antigen sensitive cell profile was determined 10 h after antigenic stimulation (Fig. 2B). As expected, a profound alteration in the pattern was observed. After stimulation for 10 h, the densest components had virtually disappeared from their usual positions and in their place two major components which banded closely together in the light density region were observed. It is probable that part of the pool of circulating cells which were sensitive to antigen had lodged in the spleen during the 10 h of stimulation. Most of the cells present in the spleen at this time, however (which on subsequent transfer with antigen gave rise to an immune response), must have represented cells which had been present before antigenic stimulation and had themselves been altered directly or indirectly by contact with antigen. It was of interest to note that the position of the two chief components of cells sensitive to antigen which had been stimulated coincided with the position of a minor component in the profile derived from supposedly unstimulated donors (Fig. 2C). Because the variation which has been observed in the profiles derived from unstimulated donors (Fig. 2C) occurs in this low density regions, it is possible that this is a reflexion of varying degrees of base level stimulation with cross reacting antigens in the donor animals.

As a further study of the effects of antigen on the population of sensitive cells, an antigen sensitive cell profile was determined in animals which had been challenged with antigen 90 days before they were killed. The results shown in Fig. 2A indicate that the components present in the profile of cells sensitive to antigen were also present in the profile of unstimulated donors. The largest part, however, of the antigen-sensitive pool of the spleen seemed to be in the low density regions characteristic of stimulated cells which were sensitive to antigen. This result is taken as evidence that low levels of antigen and therefore stimulation persisted in the spleen up until this time.

RNA synthesis and cell enlargement are known to precede DNA synthesis in the graft versus host reaction¹¹. It seemed plausible therefore that the two major components observed after stimulation for 10 h represented a separation based on differences in density between cells actively involved in RNA synthesis (G₁ state) and cells sensitive to antigen which had progressed through this stage and were rapidly dividing (S-G₂-M). Because 'Vinblastine' is known to block cells entering mitosis¹², the density distribution profile of cells sensitive to antigen was determined after antigenic stimulation in the presence of 'Vinblastine'. Fig. 3B illustrates the effect of 'Vinblastine' on the density profile when the drug was injected 7 h after antigenic stimulation. The important alteration in this profile compared with that of the control stimulated animals in Fig. 3A is a significant

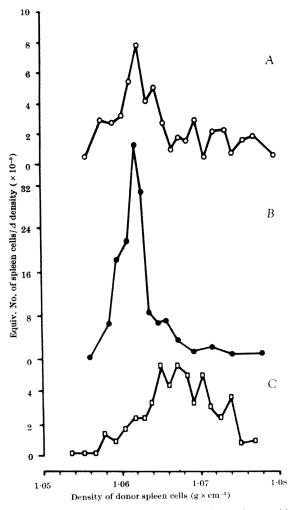

Fig. 2. Equilibrium density gradient profiles for spleen antigen sensitive cells: A, 90 days after stimulation with $2\times 10^{\circ}$ sheep red cells; B, 10 h after injection with $2\times 10^{\circ}$ sheep red cells; C, normal donor animals. From the mean titre derived from recipients of any density fraction, the equivalent number of normal spleen cells has been calculated with the aid of Fig. 1. This number has been used as a reflexion of the presence of antigen sensitive cells in each density fraction.

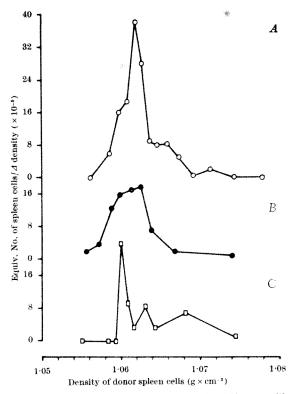

Fig. 3. Equilibrium density gradient profiles for cells which are sensitive to antigen, in the spleens of animals stimulated with 2×10^9 sheep red cells 10 h before they were killed. A, Control donors stimulated for 10 h; B, donors stimulated for 10 h but given 3 mg of 'Vinblastine' for the final 3 h; C, donors stimulated for 10 h but given 3 mg of 'Vinblastine' along with the antigen.

decrease in the major component at density 1.062. This probably reflects the elimination of cells sensitive to antigen which had entered mitosis between 7-10 h after antigen stimulation. When 'Vinblastine' was injected together with the antigen (Fig. 3C) this main component of stimulated cells which were sensitive to antigen is virtually removed, indicating that most of the antigen sensitive cells banding in this region have been stimulated into division within 10 h of injection of antigen.

Because the other stimulated component (density 1.060) did not disappear in either of these experiments with 'Vinblastine', it is concluded that this component represents cells sensitive to antigen which have been stimulated into RNA synthesis and cell enlargement but not into DNA synthesis within 10 h of stimulation.

The preliminary results presented here have indicated the usefulness of equilibrium sedimentation in analysing the lymphoid cells involved in the immune response. Although the purification achieved in Fig. 2B was fiftyfold, it was still insufficient in itself to allow a morphological identification of these stimulated cells, but it has allowed a functional identification which is probably of greater importance. Because the dual markers of function and buoyant density are used simultaneously, an absolute purification of these cells has not been needed to follow the progress of the cells which are sensitive to antigen through the various early stages of the immune response. In addition, the results have provided strong evidence for the validity of the many components which are observed on equilibrium density sedimentation not only of the antigen sensitive pool but presumably also of the various cell sources illustrated in the preceding paper.

The results presented here have been based on the assumption that only one cell population in the donor inoculum is involved in initiating and maintaining the immune response. The interpretation of the results would, of course, have to be altered if in future it is shown that two or more cell lines interact in this process.

Study of the Ag(z) Factor

The existence of a genetically determined β-lipoprotein polymorphism in human serum was detected by Allison and Blumberg¹ and Blumberg et al.², employing a precipitating antibody which was present in the serum of a repeatedly transfused patient (C. de B.) The same antiserum was investigated by Hirschfeld et al.2 and was shown to contain at least three different anti-Ag antibodies against β-lipoprotein factors which were called Ag(a₁). $\overrightarrow{Ag}(x)$, and $\overrightarrow{Ag}(z)$. Data on the genetics of the Ag(x)and Ag(a1) factors were reported by different authors4-6 who used monospecific anti-Ag(x) and anti-Ag(a₁) sera. Only one other serum (C352) was found to possess anti-Ag(z) but it also had other anti-Ag specificities7. At present, the only source of anti-Ag(z) consists of serum from C. de B. absorbed with an $Ag(x+a_1+z-)$ serum. The complicating fact is that C. de B. seems to possess a fourth antibody, so that absorption with $Ag(x+a_1+z-1)$ sera may be unsuccessful in producing specific anti-Ag(z) antiserum. It can therefore be used in immunogenetic studies only with considerable caution.

The present study is concerned with the detection of the first two examples of monospecific anti-Ag(z) sera, the distribution of the Ag(z) factor in a United States white and in an Italian population, and its segregation in families. A precipitating antibody was found in the serum of a 6 yr old thalassaemic girl (T. I.) who had received more than fifty blood transfusions (Pediatric Clinic, University of Siena, Italy). Her serum reacted with a β-lipoprotein factor which was different from Ag(a₁). Ag(x), Ag(y) and Ag(t). Sera from patients T. I. and C. de B. absorbed with an $Ag(x+a_1+z-)$ serum were tested in parallel against 250 randomly selected individuals from Philadelphia. Only two cases of discordance were observed; these may be explained on the basis of the postulated fourth antibody present in the C. de B. antiserum. A second example of apparently monospecific anti-Ag(z) was found in a 12 yr old girl with thalassaemia (C. M.), who had received more than two hundred transfusions (Children's Hospital, Philadelphia). Both these antisera were found to give precipitin bands of identity with the anti-Ag(z) contained in C. de B. when tested against Ag(z +) sera. The phenotype of T. I. and C. M. was $Ag(a_1+x+y+t+z-)$; this would permit isoimmunization to the Ag(z) factor.

ble 1. distribution of the ag(z) factor among 307 individuals living in philadelphia and 162 individuals living in northern staly

Pheno-		ales		adelphia males	Males	+ females	Northern Italy* Males + females
types	No.	%	No.	%	No.	0/ /0	No. %
Ag(z+)	39	24.68	35	23.49	74	24.10	42 25-93
Ag(z-)	119	75.32	114	76.51	233	75-90	120 74 07
Totals	158	100.00	149	100-00	307	100-00	162 100-00

* Information on sex was not available for this sample group. Comparison: Males/females, $z^2=0.059$; d.f.=1; 0.90>P>0.80. Philadelphia/Northern Italy, $z^4=0.189$; d.f.=1; 0.70>P>0.50.

The serum of the patient T. I. has been tested every 3 months for the past 2 yr for the presence of antibodies. The Ag(z) precipitin has been found in some but not all samples collected in that period. This could be a result of the fact that the Ag(z) antigen has a frequency of 25-9 per cent in the Italian population (Table 1) so that the chance of receiving transfusions of Ag(z+) blood is one in four. We observed that, in general, if a patient with iso-precipitins does not receive an incompatible blood transfusion at least every 4 months, the antibody could disappear.

The serum T. I. was employed in the Ag(z) typing of 307 non-hospitalized, unrelated, United States whites from Philadelphia, 162 Italians living in northern Italy, and 42 families comprising 84 parents and 130 children. from Seattle, Washington, who were originally collected for a study of the families of Down's syndrome patients. The frequency of Ag(z) in Down's syndrome is not different from its frequency in the general populations. (These results are now in preparation.) Table I shows the frequency of the factor in the sample groups from Philadelphia and northern Italy.

No association between sex and Ag(z) factor was observed; it does not therefore seem to be either sexlinked or sex limited in its mode of inheritance. Assuming random mating among the populations of Philadelphia and northern Italy, the gene frequencies may be obtained by the following formula: $\overline{Ag^z} = 1 - \sqrt{Ag(z-)} = 0.129$ and 0.140 respectively for the two groups.

2. COMPARISON BETWEEN THE OBSERVED AND EXPECTED PHENO-TYPIC RATIOS IN THE OFFSPRING OF THE VARIOUS MATINGS

	Mat	lings			Offsprin	g.	
Types	Nu	mber	A #	(z+)		z-)	Totals
	Obs.	Exp.	Obs.	Exp.	Obs.	Exp.	
$Ag(z+) \times Ag(z+)$	4	2.5	7	9-4	5	2-6	12 47 71
$Ag(z+) \times Ag(z-)$	15	15.3	24	25.1	23	21.9	47
$Ag(z-)\times Ag(z-)$	23	24.2	0	0	71	71.0	71
Totals	42	42.0	31		99	V # 42	1.30
Comparisons: Offspring mating	re.	$\chi_{_{5}}$	d.f.	P			
Ag(z+) × Ag(z Offspring mating	+)	0.705	1 0.50	> P > 0.3	30 (Fish	er's ex	act test)
$Ag(z+) \times Ag(z)$	(—)	0.170	1 0.70	> P > 0.5	เก		

The segregation of the trait in families is shown in Table 2. The observed frequencies in the offspring of the different matings are close to those expected on the assumption that Ag(z) is inherited as a dominant autosomal character. This genetic hypothesis was also tested using Smith's method⁸ for the analysis of the families where one or both parents were of type Ag(z+) and had at least one recessive child (Table 3). In both cases, the deviations (R_1-E_1) and (R_2-E_2) are less than the standard errors S_1 and S_2 , and χ^2 is < 1.

The only other available data on the distribution of the Ag(z) factor are those provided by Hirsehfeld et al.*, who reported a frequency of 22.45 per cent in a population of 245 individuals from Stockholm. This frequency is not significantly different from the frequency in the Philadelphia population ($\chi^2 = 0.208$; 0.70 > P > 0.50) and in these from northern Italy populations ($\chi^2 = 0.649$; 0.50 > P >0.30).

Data obtained by Hirschfeld suggest that the Ag(z) factor may be controlled by a gene $\bar{A}g^z$ which is an allele of Aqt.

We are grateful to Professor F. Ragazzini (Pediatric Clinic, University of Siena) and to Dr I. J. Wolman (Children's Hospital, Philadelphia) for serum samples of

Subcellular Localization of Entamoeba histolytica Antigen

SERA from patients with amoebiasis have been shown, by immunofluorescence, to react with smears of Entamoeba histolytica and the reaction can be prevented by absorbing the sera with centrifuged sediments of E. histolytica cultures. This investigation was designed to determine the antigenically active part of the amoeba in this connexion and the results suggest that the activity resides in subcellular cytoplasmic particles of microsomal density, which is in accord with the cytoplasmic distribu-

tion of the immunofluorescent staining.

E. histolytica, cultured in 'Bacto' endamoeba medium (Difco) with 10 per cent horse serum, were separated from most of the rice powder in the cultures by layering on 15 per cent (w/v) 'Ficoll' (Pharmacia) in mammalian Ringer solution and centrifuging at 70 g_{av} for 10 min. The lower layer was discarded and the supernatant was recentrifuged to obtain a sediment of amoebae which was washed once with phosphate-saline (0·15 molar sodium chloride, 0·01 molar phosphate; pH 7·1) and recovered by further centrifuging. In supplementary experiments, the layering on 'Ficoll' was omitted without any apparent effect on the end result. Washed, packed amoebae were broken up in a tissue grinder with a 'Teflon' pestle in tris sucrose buffer (0.02 molar tris, 0.25 molar sucrose, 0.01 molar potassium chloride, 0.005 molar magnesium chloride, hydrochloric acid added to pH 7.4) and submitted

for 1 min to ultrasound at 20 ke/s by the MSE ultrasonic disintegrator, operated at 500 W. Disruption of amoebae was confirmed by light microscopy, and fractionation was carried out by differential centrifugation. The first sediment, collected after centrifuging at 350 gav. for 15 min, contained nuclear material and coarse cellular debris, together with clumps of bacteria and rice grains from the original culture medium. The supernatant, centrifuged at 6,500 g_{av} for 30 min (Servall $R\hat{C}$ -2, SS 34 rotor), yielded a second sediment consisting largely of membranous material and bacteria. Centrifugation of the second supernatant was carried out at 105,000 gav. for 60 min (Spinco L-2, type 50 titanium rotor) to yield a third sediment ("microsomal") and the final supernatant constituting the cell sap. These procedures were carried out at 0°-3° C and all sediments were washed once by resuspending in the tris buffer and recentrifuging.

Suspended in original homogenate volume.

Serum absorption was carried out by incubating a volume of serum with an equal volume of final supernatant cell sap, or of sediment suspended in tris buffer to one-twentieth of the volume of the original homogenate: 1 in 2 and 1 in 20 dilutions of this suspension were also tested, the latter dilution making the same volume as the original homogenate. One absorption was carried out at 37° C for 1 h and a second was carried out overnight at 2° C: the serum was recovered after the absorptions by centrifuging at 7,000 gay. for 30 min. The results of absorptions on the capacity of the sera to produce immunofluorescent staining of amoebic smears, summarized in Table 1, show that the antigenic part of the homogenate is very largely confined to the third sediment, which is of microsomal density. The other two sediments and the cell sap possess little antigenic activity.

Samples of the sediments and of intact amoebae were examined by electron microscopy. Pellets of material

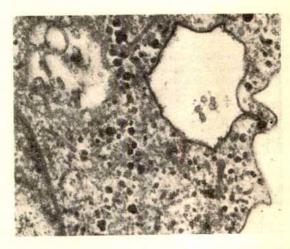

Fig. 1. Electron micrograph showing part of intact E. histolytica including quadrant of nucleus (bottom left), phagocytic vacuole (top right) and plasma membrane (extreme right). The black bodies in the granular cytoplasm have the appearance of glycogen; granular rod-like structures and (top left) small membranous vesicles are also present. ($\times 24,000$.)

Fig. 2. Subcellular fraction (third centrifuged sediment) of E. histolytica culture showing microsomal vesicles among the granular cytoplasmic material. ($\times 24,000$.)

were fixed in 2.5 per cent glutaraldehyde in sodium phosphate buffer (0.1 molar, pH 7.2), fixed in 1 per cent osmium tetroxide in the same buffer, dehydrated in acetone and embedded in 'Araldite'. Sections about 500 Å thick were mounted on carbon coated grids and stained successively with uranyl acetate and lead citrate. The antigenically active third sediment consisted of granular material and membranous vesicles corresponding to similar material in the cytoplasm of the intact organism (Figs. 1 and 2). Ribosomes could not be positively identified; structures resembling rods found in the intact organism could not be found after fractionation. Electron microscopy of the antigenically inactive first and second sediments confirmed the appearances seen by light microscopy. Among the bacteria and membranes of the second sediment there were many large vesicles, although mitochondria and Golgi bodies were not identifiable, which is in accord with observations on the intact organism by ourselves and

The exact nature of the antigenically active material is uncertain, but it is not nuclear and does not seem to be associated with surface membranes or large vesicles; it includes small vesicles and corresponds to the microsomal fraction of mammalian cells. If it can be concluded that intracytoplasmic material rather than surface membrane plays the principal antigenic part in amoebiasis infection, it could be inferred that immunological stimulation by disrupted organisms is the chief source of the serum antibody in human infection. Relative absence of antibody against surface components could be one explanation of the failure of an otherwise active immune response to prevent local invasion by the parasites in the disease.

Number of Antibody-forming Cells in Primary and Secondary Reactions after Administration of Antigen

When newborn animals are immunized with a bacte antigen, large quantities of the antigen must be injecto elicit a primary antibody response1,2, Similarly, primary antibody response is induced in newborn rabl or in sterile piglets by sheep erythrocytes, the amount antibody in the serum and the number of antibody-fo ing cells in the spleen are greater the more antiger used3,4. In the true primary response, administration a 75 per cent lethal dose (100 ml. of concentrated susp sion of sheep erythrocytes given intraperitoneally sterile piglets, that is, 2×10^{12} cells) did not immedia inhibit antibody formation. On the contrary, number of cells producing haemolytic 19S and 7S a bodies is estimated after the intravenous administra to sterile piglets of very large quantities of the anti (20 ml. of a concentrated suspension of sheep erythrocy that is, 4 × 1011 cells), the number of antibody-forn cells in the spleen, where antigen is predominantly lo ized, is greater than when a similar dose is given i cutaneously or intraperitoneally (Fig. 1). shows that the inductive phase—when no antibody-fe ing cells are detected—lasts 36 h. After this period, t is a rapid increase in the number of antibody-form cells, at first with a doubling time of 2.6 h, later of 3 This cannot be considered to result from cell divi only. As suggested earlier4, it is supposed that the antibody-forming cells are thought to be formed differentiation of preformed competent cells and that rapid increase in the number of antibody-forming results from direct asynchronous differentiation of pre-existing competent cells. The very small number immunocompetent cells in lymphoid tissue (approxima one cell/106 lymphoid cells) explains the need to use quantities of the antigen to evoke a true primary reas in newborn animals. To make possible chance cor between the few immunocompetent cells and a cri quantity of antigen, substantially more antigen is quired than in the hypothetical case when nume competent cells are present (Fig. 2). The number of reacting with the antigen during the secondary reac was found to be greater by at least two orders of magni than the number of cells involved in the primary tion6. For simplicity, it is assumed that antigen ha same role in the primary and the secondary reactions this assumption, to activate the same number of ce the secondary as in the primary reaction, the amou antigen which would suffice would be inversely pro tional to the number of reacting cells in lymphoid ti

If a constant quantity of the antigen is require activate each immunocompetent cell, the probabili

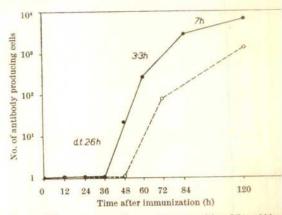

Fig. 1. Primary response after very large quantities of the red bloo antigen (20 ml. of concentrated suspension of sheep erythrod 4×10¹¹ cells) by intravenous (●) and subcutaneous (○) injection

 a_t is the concentration of the antigen at time t, and C is a constant (given by the experimental system used).

If N immunocompetent cells are present at immunization, then $n_t = N.P_t$ cells from these N cells will have contact with the antigen during time 0 to t. For a sufficiently large value of t, and on the simplified assumption that the concentration of the antigen decreases exponentially with time, Fig. 3 shows how the average number of antibody-forming cells will depend on the quantity of the antigen injected for three populations of immunocompetent cells of increasing size $(N_1 < N_2 < N_3)$. The number of antibody-forming cells increases linearly with the increasing dose of the antigen; only at very large doses of antigen does the rate of increase of antibody-forming cells slow down;

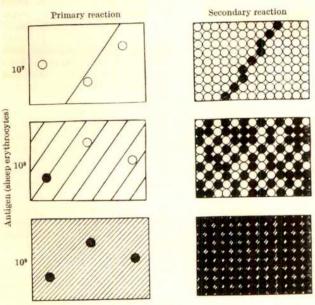

Fig. 2. Model of relationship between the number of competent cells and the quantity of antigen.

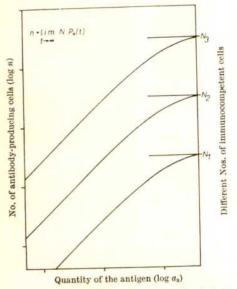

Fig. 3. Scheme of the dependence of the number of activated immunologically competent cells n on the antigen dose a_0 .

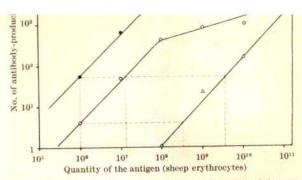

Fig. 4. Quantity of antigen necessary for the formation of the same number of antibody-forming cells during primary and secondary reactions.

4. Primary response. Secondary response: O, complement only (198); , complement plus anti-IgG serum.

it ceases when almost all immunocompetent cells are activated.

These assumptions were tested by estimating the number of cells responding after induction of primary and secondary response in sterile piglets fed a non-antigenic diet7. A group of 7 day old piglets was immunized with various amounts of sheep erythrocytes (Table 1). Only after the injection of more than 2 × 108 sheep erythrocytes can a primary response be detected; after increasing the dose of the antigen injected, more antibody-forming cells are detected during the primary response. Another group of piglets was prepared for secondary response by immunization on the seventh day of life with 2×109 sheep erythrocytes. This dose caused a low primary response, which disappeared during 3 weeks, at which time the animals were re-stimulated. Before stimulation neither antibody-forming cells nor serum antibodies were detected. The animals were stimulated again with various doses of the antigen, as in the primary stimulation. In comparison with the primary response a similar number of cells forming 19S antibodies was detected in the secondary reaction when the amount of antigen was more than two orders of magnitude smaller. A quantity of antigen three orders of magnitude smaller sufficed (Fig. 4) to detect cells forming 7S antibodies (using anti-IgG serum).

Table 1, RELATION BETWEEN THE QUANTITY OF THE ANTIGEN AND THE NUMBER OF ANTIBODY-PRODUCING CELLS IN PRIMARY AND SECONDARY REACTIONS

The dose of sheep erythrocytes injected I.p.	Primary response in newborn piglets (7 days after antigen injection)	piglets primary birth with 10° s Antibody-produ	nse of 1 month old stimulated after heep erythrocytes. cing cells detected jection of antigen By anti-IgG serum and complement (7S)
2×10^{6} 2×10^{7} 2×10^{8} 2×10^{9} 2×10^{10} 2×10^{14}	0	4	56
	0	48	640
	1	416	3,600
	22	800	8,000
	162	1,040	20,000
	1,861	3,030	30,060

These results indicate that a hundred times as many more cells producing 19S antibodies and a thousand times as many producing 7S antibodies are detected in the secondary response as in the primary response. Within certain limits of antigen dose, the results correspond to the suggested equation (1), that is, there is a linear dependence of the quantity of the antigen on the number of cells detected (one-hit system). The linear relation is valid in the primary reaction for a wide range of antigen doses, but in the secondary reaction it is valid up to the critical point of saturation only. This indicates

a difference in the capacity of antigen to bind to cells which react in the primary and the secondary reaction.

PATHOLOGY

Facilitation of Tumour Growth by Bacillus pertussis

SEVERAL Gram negative bacteria or their components can exert a slight but significant inhibitory effect on the growth of tumour isografts1-4. Protection is obtained by administering the bacterial product at various times before the inoculation of the tumour cells. It is thought that these agents cause non-specific stimulation of the immune response against tumour-specific antigens.

On the other hand, bacterial products have been shown to inhibit manifestations of cellular immunity when applied simultaneously with the antigen. The tuberculin reaction in guinea-pigs and a normal lymphocyte transfer reaction in chickens were clearly reduced by concomitant administration of B. pertussis vaccine or extracts, and by microgram quantities of S. paratyphi B and S. typhosa extracts 5-7, whereas previous administration of these agents tended to enhance the two reactions. We have therefore investigated whether Gram negative bacteria have an inhibitory effect in a system involving transplantation immunity

against tumour isografts.

The experiments were performed with 6-8 week old inbred mice of the C57L/KL strain, weighing 16-20 g. Mice of both sexes were randomly placed in control and experimental groups. The experiments were carried out with Moloney lymphoma isografts. The tumour cells were obtained from a YLI lymphoma line propagated in C57L/KL mice at this institute. The solid lymphomas were excised, cut into small pieces, forced through a 60-mesh stainless steel screen into balanced salt solution (BSS) and filtered through gauze. The concentration of viable cells was estimated by the eosin exclusion method. Graded doses of tumour cells in 0-1 ml. of BSS were injected subcutaneously. The inoculum was placed midway between the axilla and the last rib of the mice. The development of the tumours was followed by bi-weekly measurements with a calliper in its long axis and in a direction perpendicular to this. Tumours were recorded as takes as they became and remained palpable. If the inocula took in the recipients, three different patterns of tumour development were seen. (1) Progressive growth to large-sized masses of about 30 mm average diameter. with the mice dying after about 2 months. (2) After an initial growth of up to 8-10 mm average diameter, a total regression of the local turnour could occur. The regression was considered to be complete if the mice survived until the end of the experiment at day 110 without macroscopic evidence of leukaemia at autopsy. These mice were recorded as negative when any palpable tumour nodes had disappeared. (3) In some cases, the regression of the palpable local tumour was followed by the development of generalized leukaemia. These mice became emaciated and ultimately died showing massive generalized lymphadenopathy. In these mice, the tumours were recorded as takes throughout the experiment.

Within 30-60 min after the inoculation of the tumour cells, 0.1 ml. of B. pertussis vaccine (Statens Bakteriologiska Laboratorium, No. 295) was injected intraperitoneally into the mice of the experimental groups. vaccine contained 20 × 10° bacteria/ml. of saline to which 0.01 per cent merthiolate had been added. Control mice were injected with 0.01 per cent merthiclate in 0.1 ml. of

In analogous experiments, the following tumours were also inoculated into isogeneic hosts: the Moloney lymphoma lines YAC-IS (into A/Sn mice), YBA, YBB and YBC (into CBA), the methylcholanthrene-induced sarcoma MSB (into $[A.BY \times A/Sn]$ F_1 hybrids) and the polyoma tumour line SEWA (into A.SW/Sn/Kl mice). With the latter, cells were obtained from a tumour maintained by subcutaneous transplantations for thirteen generations in A.SW/Sn/Kl mice. The polyoma tumour was cut into small pieces and incubated with 0.5 per cent trypsin for 20 min at room temperature with continuous stirring. The cell suspension was then washed with BSS and adjusted to a concentration of forty viable cells/0-1 ml., the dose which was injected subcutaneously into the A.SW/Sn/Kl recipients. One group received B. pertussic vaccine intraperitoneally as in the experiment with YLI. whereas to the second experimental group 1 mg/kg of crude extract from B. pertussis culture broth was administered by the same route. Tumour development was followed as described for the YLI lymphomas.

It can be seen from Table 1 that the administration of B. pertussis vaccine concomitantly with the inoculation of 104-106 YLI cells led to an increased incidence of turnour This increase was most pronounced about 2-3 weeks after implantation of the turnour. Subsequently, in the mice transplanted with 105 cells, the difference tended to decrease as a consequence of the more delayed occurrence of tumour in the controls and the higher rate of complete regressions in the group treated with B. pertussis. As to the final outcome, the difference was most marked after the inoculation of 106 YLI cells (8/15 takes versus 0/14 in the control group). If the cumulative incidence of tumours was considered, the difference was statistically significant in the groups inoculated with 104, 105 and 105 YLI cells. Initially, the average tumour diameters were smaller in the control groups, but the final survival time of the mice bearing tumours was not significantly different between experimental and control groups. In exploratory

tests with the other tumours listed, B. pertussis vaccine did not cause increased incidence of tumours, except for the SEWA polyoma tumour, where a similar trend as in the YLI lymphoma was observed (Table 2).

It is interesting that in the control groups inoculated with 104 or 105 YLI cells there was a higher incidence of tumour takes than in the group receiving 106 cells. Similar observations have been described with the transplantation of sarcomas induced by methylcholanthrene³. It is tempting to ascribe this phenomenon to the "sneaking through" mechanism, allowing small numbers of tumour cells to escape host defence reactions at a critical time, whereas medium sized inocula (106 cells in our case) would elicit a more powerful and effective immune response. With still larger cell doses (107), a breakthrough of tumour growth, overwhelming host resistance, might account for the high incidence of tumours.

To extend these preliminary observations, it will be necessary to assess the effects of bacterial products of other origin, of their dosage and of the time of application. It is conceivable that the same bacterial product might inhibit or promote tumour growth according to these criteria.

If one considers that the Moloney lymphomas in C57L/KL mice show the greatest immunosensitivity both in vivo and in vitro among the Moloney lymphomas tested 10 and also that the SEWA tumour has a relatively strong immunosensitivity11, it would seem that the observed effect occurs only if an immune response of some strength is involved. As to its mechanism, one possibility is the enhancement of tumour growth. The adjuvant effect of the pertussis vaccine on humoral antibodies might lead to their unusually early formation. assumption is unlikely, however, in the light of the high sensitivity of the YLI tumour to humoral cytotoxic action (personal communication from G. Klein). Alternatively, the transient inhibition of phagocytosis occurring after endotoxin administration¹², or, more likely, antigenic competition or "preoccupation" of some component of the immune response, ought to be considered. importance of timing and dosage is also emphasized by an observation made in another, but probably related context. If mice are treated with B. pertussis vaccine or S. typhosa lipopolysaccharide a few hours before infection with other bacteria, their susceptibility to infection is heightened, while pre-treatment at a longer interval increases resist-Furthermore, fractions of M. tuberculosis in certain doses can accelerate the appearance of isogeneic tumours if administered even some weeks before their transplantation. Thus micro-organisms, including bacteria, bacterial substances and viral agents14, may temporarily depress the immune response by a non-specific mechanism the nature of which is unknown. Perhaps it could be that a selective advantage would be conferred on micro-organisms by an inherent immunosuppressive capacity of some degree.

This is additional evidence for the inhibitory effect of B. pertussis vaccine on the outcome of a cellular mediated immune response. For practical purposes, the observation that states related to the presence of vaccines or infective agents can, in certain conditions, facilitate the growth of relatively small numbers of malignant cells clearly deserves further investigation.

I thank Professor George Klein for his hospitality, for valuable discussions and for reviewing the manuscript. Sequential Biochemical Alteration to Antifolate Resistance in L1210 Leukaemia

Antifolate resistant, transplantable, murine tumours are most often characterized by a single change involving either the transport of drug¹ or the level of dihydrofolate reductase²⁻⁵. This is understandable if one accepts the idea that multiple genetic events leading to an involvement of more than one physiological site rarely occur simultaneously. In two cases, where both physiological properties were altered^{6,7}, the development of resistance probably occurred in a step-wise manner⁸. demonstrated this type of sequential alteration in resistance at both the physiological and cytogenetic level during repeated transplantation of a subline of L1210 leukaemia.

An antifolate resistant subline of the parental line V was selected by transplantation in $BD\hat{F_1}$ mice during combination chemotherapy with amethopterin (0.75 mg/kg), 6 mercaptopurine (6.25 mg/kg) and 5-fluorouracil (10 mg/kg). Although this line, L1210/A/MP/FU (XVI₄), was resistant to all three drugs within several transfer generations^{5,10}, maintenance under the same chemotherapeutic conditions resulted in a population shift at some time between transfer generation 153 and 191 to a cell type lacking the subtelocentric (ST) marker chromo-Preservation of frozen ascites at different transfer generations enabled us to reinitiate the subline at generation 153 and to examine it concurrently at both karyotypic stages for 3H-amethopterin transport and dihydrofolate reductase activity. Cells were collected on the sixth day after transplantation for karyotype analyses10 and on the seventh day for measurements of 3H-amethopterin uptake 12 and the preparation of enzyme extracts 12 . The determination for dihydrofolate reductase activity was described elsewhere13. For measurements of 3H-amethopterin uptake, 2×107 cells in modified Eagle's minimal medium¹⁴ (pH 7·5) were incubated with ³H-amethopterin (1.35 mc./mg) at both 0° C and 37° C. Methods used for the removal of external radioactivity by washing, the extraction of labelled drug and the counting of radioactivity have been described 15. Results are summarized in Table 1.

The level of dihydrofolate reductase in cells of subline $\mathrm{XVI}_4\left(ST^+
ight)$ at transfer generation 153 was like that of the parental line V. Following a shift in the population to the ST- cell type, the enzyme level rose twelve times. This increase was similar to that reported earlier^{5,10} for a related ST- subline. The rise in enzyme level in the altered subline XVI, was verified by titration for enzyme

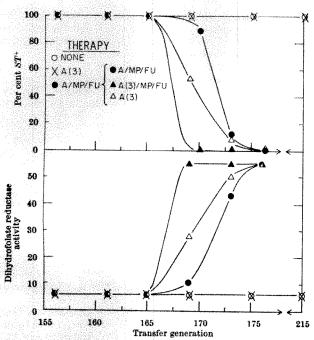

Fig. 1. L1210 leukaemia cell population change $(ST^+ \rightarrow ST^-)$ during transplantation of subline XVI, and the effect on the dihydrofolate reductase level. The subline was reinitiated at generation 153 and chemotherapy begun at generation 154; A, amethopterin, 0.75 mg/kg; A (3), amethopterin, 3 mg/kg; MP, 6-mercaptopurine, 6-25 mg/kg; PU, 5-fluorouracil, 10 mg/kg; the subline exposed to the A/MP/FU combination was divided into three branches at generation 165 and the three forms of therapy begun at generation 165 forms of therapy begun at generation 165. three forms of therapy begun at generation 166

in each of the three preparations based on the binding of amethopterin 16. The uptake of 3H-amethopterin by L1210 leukaemia cells occurs principally by active transport. An experimental description of this system will be published elsewhere12. The rate of uptake of 3H-amethopterin at 37° C by cells of all three lines was linear for at least 15 min. Cells of the unaltered subline XVI, (ST^+) transported 3H-amethopterin at a rate four times lower than cells of the parental line V. Following alteration of the line $(ST^+ \rightarrow ST^-)$, however, the rate of transport was normal. Lineweaver and Burk's¹⁷ analysis of 3H -amethopter in transport demonstrated Michaelis-Menten kinetics for all three systems. The K_m for the system in both ST^+ and $ST^$ resistant cells was three times greater than that calculated for the system in the parental cells. This is taken as evidence for a reduced binding affinity of some carrier component and explains the lower rate of transport in the ST+ cell. Because the same reduction in binding affinity was also characteristic of the carrier in the ST cell, we conclude that the system in this cell type was similarly altered (that is, the impairment is unrelated to the presence or absence of the ST chromosome). The normal rate of transport in this line was probably caused indirectly by the binding of more drug by an increased level of dihydrofolate reductase. The selective advantage determined by the increase in dihydrofolate reductase was thus diminished by an "indirect" restoration of a prior impairment.

BIOLOGY

More Humane Way with Seals

From July 12 to July 27, 1967, I visited St. Paul I Pribilof Islands, Alaska, USA, to observe part annual harvest of northern fur seals, Callorhinus un and to evaluate the killing methods which were

The outdoor temperature there in mid July is about 50° F. I watched the herding and driving of non-breeding male fur seals from their hauling grounds on the beaches to the fields behind the beaches where they are killed. distance over which the animals were driven varied from a few hundred yards to half a mile or so. I observed the killing of 3 and 4 yr old male fur seals with hardwood clubs 155 cm long which weighed 2.2 kg. These clubs were wielded by five men, known as "clubbers", who were the most experienced and most highly paid members of the sealing crew. Seals in groups or "pods" of about ten would be driven from the chief herd towards the clubbers, who accurately clubbed each seal once on the top of the head. Occasionally, if the blow was not apparently accurate, the seal was hit on the head a further blow or blows. The clubbed seals were then laid in a row and a man known as a "sticker" would carefully incise the skin in the mid-ventral line to the mid-sternal region and thrust the knife through the costochondral junction into the thorax, aiming at the heart. The seal would then be skinned by another group of men.

I conducted post-mortem examinations on a sample of 1,121 fur seals treated in this manner. This sample was taken from a total number of 16,578 fur seals killed during my 2 week stay on the island. The method of examination was first to examine the skulls for signs of gross fracture and bruising and then to examine the thorax to determine the extent of haemorrhage into the pleural and pericardial cavities, and to determine whether or not the myocardium was punctured. The lungs of 418 animals were examined to determine the presence or absence of gross

emphysema.

From the accompanying table of results, it can be seen that a total of twenty-one or 1.9 per cent of the skulls which I examined showed no fracture of the cranium, and thirty-eight or 3.4 per cent of hearts were not punctured. The thorax of every fur seal carcass which I examined, however, had been opened, and this would lead very rapidly to death from respiratory failure, had the animal not been killed by either the blow to the head, or by cardiac puncture. I found no evidence that any fur seal

had been skinned while still alive.

Comparing these observations with similar observations on the Harp Seal hunt in the Gulf of St. Lawrence¹ it can be seen that whereas 1.9 per cent of 1,121 crania examined on the Pribilof Islands were found to be unfractured, 36 per cent of 154 crania examined in the Gulf of St. Lawrence were found to be unfractured. There seem to be several factors contributing to this difference. In the Pribilof Islands, sealing takes place on land, at temperatures of about 50° F. The men clubbing the seals are a small group of experienced men working under close supervision, supported by a team of workers who complete the operation. The sealers work only a few hours each day (from 2 to 6 h), have frequent breaks for refreshment, and are salaried employees. Sealing takes place over a period of about 6 weeks, and of the order of 60,000 seals are taken annually. In contrast, in the Gulf of St. Lawrence, sealing takes place on broken sea ice at temperatures below freezing. The Gulf seal hunters are untrained in the killing of animals and each man both kills and skins the harp seal pups. The annual quota of 50,000 is taken in 3 to 5 days, during which time about 600 sealers work independently with virtually no supervision. The large number of men working over a large area of broken ice presents a formidable barrier to effective control. The sealers work from 6 a.m. to 6 p.m. every day during the hunt and are paid by the piece.

In my opinion, the striking contrast between these two sealing operations, involving the northern fur seal on the

Pribilof Islands and the harp seal in the Gulf of St. Lawrence, indicates that as long as the present structure of exploitation of the harp seal in the Gulf of St. Lawrence remains, humane killing does not seem likely.

The expedition to the Pribilof Islands was financed by the World Federation for the protection of animals. thank the US Bureau of Commercial Fisheries, Department of the Interior, for assistance. Mr P. R. Simpson arranged the expedition and assisted at the post-mortem examinations.

Oxidation of Sulphonic Compounds by Aquatic Bacteria isolated from Rivers of the Amazon Region

THE sulphonic group has been found as a component of aliphatic compounds in plants and algae1-5. The metabolic fate of sulphonic compounds in micro-organisms has been so far the only available means of studying their transformation in nature^{6,7}. As well as the importance of this information for a general understanding of the biochemical pathways of living organisms, there is also the question of the increasing use of sulphonic detergents and their release in sewages and soils. Their biodegradation depends on the ability of micro-organisms of soil and water to oxidize them. Previous work has shown that soil and water poor in vegetable residues, such as that near big cities like Rio de Janeiro, contain very few bacterial strains able to carry out this degradation. Only a few such bacteria were found in soil samples, and no bacteria able to oxidize sulphonic compounds were found in water samples7.

The rivers in the Amazon region are very rich in materials of vegetable origin, and so we have looked for these bacteria and describe our results here.

Samples were collected from the Negro River, the Amazonas River, the Guamá River and the Paracauaú River. 3-Sulpho-1,2-propanediol (SPD) was selected as a representative of a sulphonic vegetable compound. The barium salt, prepared by M. Miyano, was transformed to the sodium salt and used throughout the experiments. SPD labelled with sulphur-35 was prepared by A. A. Benson from the iodine-1,2-propanediol and monobasic potassium sulphite labelled with sulphur-35. Some synthetic sulphonic compounds were also tested; these were N-tris(hydroxymethyl)l-methyl-2-aminoethanesulphonic acid (TES); N-(2-sulphoethyl)-morpholine (MES); N-(3sulphopropyl)-morpholine (MOPS); N-(2-hydroxyethyl)-, N'-(2-sulphoethyl)-piperazine (HEPES); and N-(2-hydroxyethyl)-,N'-(3-sulphopropyl)-piperazine (HEPPS).

For the bacteria we used the enrichment culture techniques, followed by the isolation and classification of the bacterial strains by classical procedures. The bacteria were tested for their ability to grow aerobically at 30° C, on the specific substrate as the only source of earbon and sulphur. In some experiments, the synthetic compounds were also assayed as the only source of nitrogen, as well as the only source of carbon and sulphur. In one set of experiments, $1.0 \mu g$ of vitamin B_{12} was added to each 1 ml. of medium. Growth was measured by the relative increase in cell volume. Non-proliferating adapted cells, obtained by centrifugation during the exponential growth phase, were washed three times with 0.02 molar trishydrochloric acid buffer (pH 7.4) and resuspended in the same buffer. The radioactivity was measured in a Nuclear Chicago scintillation counter.

Bacterial strains growing on SPD were isolated from all the samples tested, when the cultures were kept at

Number of seals taken between July 14 and July 26, 1967 Number of seals examined at post mortem 16,578 1.121

Number of unfractured crania 21 (1.9%)

Number of hearts not punctured 38 (3.4%)

Table 1. DISTRIBUTION OF METABOLIC PRODUCTS FROM 34S-SULPHOPROPAN-

Fractions	$c.p.m. \times 10^8$	Per cent
Initial activity	2,400	100
Supernatant solution	580 1.520	24 63
Cells Alcoholic extract	1,520 55	2

30° C. At 24° C they do not grow on the selective medium after a week of incubation. The strain was tentatively classified as a species of Pseudomonas sp. and was used to oxidize labelled SPD in non-proliferating conditions. The reaction mixture contained 2 mg of cells suspended in 1.0 ml. of 0.02 molar tris hydrochloric acid buffer (pH 7.4), 20 µmoles and 2,400×103 c.p.m. of labelled SPD, and distilled water to 2.0 ml. After 4 h of incubation at 37° C and aeration, the cells were centrifuged, washed and extracted with hot 80 per cent ethanol. The radioactivity was counted in the whole cells, in the supernatant and in the alcoholic extract. The results are presented in Table 1.

The distribution of radioactivity showed that the sulphur from the SDP was accumulated chiefly in the in-

soluble fraction where proteins are found.

Two dimensional paper chromatography was carried out with the alcoholic extract on Whatman No. 1 paper, in phenol-water (100:40 w/w) and n-butanol-propionic acid-water (142:71:100, v/v). Three radioactive spots were detected: one, at the origin, was identified as free sulphate by paper electrophoresis⁶; the second was identified as SPD by co-chromatography with the authentic standard; the unknown spot is probably an intermediate and is not yet identified.

The synthetic compounds MES, MOPS, HEPES and HEPPS were able to support the growth of the species of Pseudomonas isolated from the SPD medium after 48 h of incubation at 30° C as long as there was a source of nitrogen. When the medium lacked this source there was no significant growth. The compound TES was a better source of carbon and sulphur than the others, for there was full growth after 18 h of incubation.

Addition of vitamin B₁₂ did not affect the utilization of the assayed compounds in any way. The blanks with the mineral medium and the vitamin did not show any growth.

I conclude that in the microbiological flora of waters enriched by vegetable residues, as in the rivers of the Amazon region, there are bacterial strains able to control the induction of the enzymes which catalyse the oxidation of sulphonic compounds. These bacteria allow natural sulphonic compounds, as well as synthetic ones, to participate in the natural cycle of the elements, releasing their carbon and sulphur in chemical forms available for utilization in other living processes.

This work was undertaken when I took part in the Amazon expedition on the RV Alpha Helix, operated by the Scripps Institution of Oceanography, University of California, San Diego, and was supported by grants from the US National Science Foundation and the National Research Council of Brazil. I thank Dr Andrew A. Benson, who encouraged this work, and Dr M. L. Ibanez for

collecting some samples.

Is an Ectoproct Possible?

Mangum and Schopf1 claim on the basis of their calculations that the diffusion of oxygen into the body of an ectoproct is insufficient to supply the animal with its respiratory needs. They conclude that the periodic contraction of an ectoproet circulates its coelomic fluid. I believe their calculations are incorrect and that diffusion of oxygen into the ectoprocts is sufficient to supply their needs.

Their calculations are based on a formula from Gerard* for calculating the amount of oxygen which can diffuse into cylindrical tissue, the tentacles and the tentacle sheath. Gerard made a mistake in deriving his formula in that he used $A\pi r^2$ to represent the amount of oxygen required by a unit length of cylinder of radius r where A is the oxygen consumption of unit weight and time. To be correct, either the density of the tissue must appear in the formula or the oxygen consumption must be in terms of unit volume and time rather than weight and time. The complete formula takes the form

$$C = \frac{Ar^2}{4\overline{D}}$$

where C is oxygen concentration at the external surface. A is the rate of oxygen consumption and D is the diffusion coefficient for oxygen. This is dimensionally correct when C is ml./ml., A is ml./ml. sec, r is cm and D is cm²/sec. The density of tissue is very close to one, and so the error introduced by using oxygen consumption on a wet weight basis rather than a volume basis is usually insignificant. Unfortunately, among the papers on oxygen diffusion into cells, Fenn³, Gerard², Krogh⁴ and Harvey⁵, only Harvey makes explicit the assumption of a density of one.

Mangum and Schopf express C in atm.; A in mm³/mg dry weight min, r in cm and D in atm./cm/cm². Using these units it is impossible to make any kind of sense out of the

equation because it reduces to atm. =
$$\frac{\text{min /oss}}{\text{atm./mg/min}}$$

Part of the difficulty lies in the units assigned to D which in modern literature usually represents the diffusion Mangum and Schopf are using something coefficient. often called the permeability coefficient, the diffusion Instead of coefficient multiplied by the solubility. atm./cm/cm² as they state, their number has the dimensions cm²/atm./min. The dimensions are clear in Krogh from whom they obtained their numbers. Unfortunately, Krogh6 later used atm./cm/cm2 as if it were the units of permeability although it actually refers to the conditions of the measurement: the flux measured through an area of 1 cm² with a gradient of 1 atm./cm.

When the calculations of oxygen diffusion into the ectoproct are made on the correct volume specific basis the results are about 100 times larger than those calculated by Mangum and Schopf for the tentacles and sheath. Even their results, however, are large enough to account for the oxygen consumption of those parts of the animal entirely on the basis of supply by diffusion.

The critical part of the animal is the zoecium which they maintain needs 300 times more oxygen than can be supplied by diffusion. For the calculation they use the formula

$$C = \frac{Ad}{D}$$

in which d is the depth of the zoecium in cm and the other symbols are as before. With the correct units for permeability, D, the equation gives $C \text{ cm}^3/\text{cm}^2 \text{ min which is}$ equivalent to mm³/mm² min. Mangum and Schopf called their results mm³/mg h, with the consequence that, when the value for the zoecium as a unit was calculated, their value was 1,000 times too small. The dry weight of the zoecium was about 10-3 mg and the frontal area through which diffusion occurs was about 1 mm2.

The correct values are given in Table 1 and compared with the results of Mangum and Schopf and with their values for the oxygen consumption of the animals. (The correct values are calculated with an oxygen pressure of 0.21 atm. which corresponds to that in water in equilibrium with air, not the value of 0.29 used by Mangum and Schopf which corresponds to considerably oversaturated water. It should also be noted that this is not a measure of oxygen concentration as they state, but of the pressure which together with the solubility determines the concentration.)

Table 1. SUMMARY OF CALCULATIONS OF OXYGEN DIFFUSION IN A SINGLE ECTOPROCT

Part of animal	Oxygen supply by diffusion Calculation of Mangum and Schopf (mm²/h×10-²)	My calculation mm³/h × 10-2	Observed oxygen uptake from Mangum and Schopf mm³/h × 10-2
Lophophore	23·9	280	0.026
Tentacle sheath	0·3	3·6	0.029
Zoecium	0·004	2·0	0.37

These data are after Mangum and Schopf, who called attention to the misprint in the original table for their calculation for the zoecium.

It can be seen from Table I that the zoecium can be supplied with oxygen by diffusion with only a 20 per cent reduction in partial pressure of oxygen at the back wall, the point farthest from the water. There is no reason to assume circulation of the fluid within the body is necessary to satisfy the oxygen needs of ectoprocts.

CYTOLOGY

Nuclear Pockets in Normal Monocytes

NUCLEAR pockets (or nuclear blebs, nuclear loops) have been described in leukaemic cells in different treated and untreated leukaemias1-4, and their specificity for leukaemic

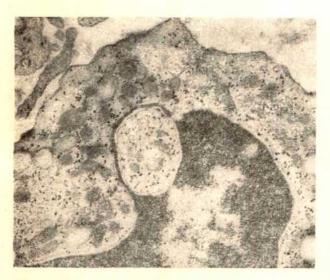

Fig. 1. Nuclear pocket in neutrophil leucocyte of peripheral blood

Fig. 2. Nuclear pocket in normal monocyte of peripheral blood (×16,000).

cells has been discussed. They are similar to the material joining nuclear lobes of segmented granulocytes. Smith⁵ has demonstrated nuclear pockets in non-leukaemic lymphocytes.

We have frequently found nuclear pockets in lymphocytes, neutrophils (Fig. 1) and also in monocytes (Figs. 2 and 3) of healthy subjects. Nuclear pockets can therefore be considered not to be specific for leukaemic cells. They seem to be a physiological structure in all forms of leucocytes. Nuclear pockets may have the function of enlarging the surface of the nucleus-they are not necessarily a malformation of the nuclear envelope.

MICROBIOLOGY

Acetylene Reduction by Nitrogen Fixing Extracts of Clostridium pasteurianum: ATP Requirement and Inhibition by ADP

NITROGEN fixing extracts of Clostridium pasteurianum have been shown to catalyse the reduction of acetylene1.2. The requirements for this reaction were shown to be the same as those for nitrogen fixation, that is, a low potential electron source, ATP, an ATP generating system and magnesium ions. Acetylene reduction provides a more sensitive assay for the activity of the nitrogen fixing system than ammonium production and the measurement of rates of reactions is facilitated. The results described in this communication show that the reduction of acetylene by these extracts can be supported directly by ATP without an ATP generating system. When an ATP generating system is not used we now find that (a) magnesium ions are required for ATP utilization by the nitrogen fixing system, a fact not previously demonstrated, for magnesium ions were required for the ATPgenerating system; that (b) the acetylene reduction by the nitrogen fixing system is inhibited by ADP in a manner which suggests that ADP is a negative modifier; and that (c) the acetylene reducing system needs to interact with more than one molecule of ATP.

C. pastcurianum was grown in a nitrogen-free medium under nitrogen and extracts were prepared from dried cells in 0.05 molar tris hydrochloric acid buffer (pH 8)3; partially purified molybdoferredoxin and azoferredoxin were prepared by the method of Mortenson, Morris and Jeng. The rate of reduction of acetylene to ethylene was determined by gas chromatography using a 72 cm column of 1.5 mm diameter containing 'Poropak R' (Varian Aerograph Co., California). Nitrogen was used as carrier gas at room temperature using a hydrogen flame ionization detector. The reaction was carried out at 30°C in 10 ml. serum bottles and gas samples were taken using a gas-tight syringe. The reaction mixture (a total volume of 2 ml.) contained 115 µmole potassium cacodylate (pH 6-8), the appropriate amount of MgCl, and ATP, and 0.5 ml. extract (14-18 mg protein). When partially purified components were used the extract was replaced by 0.15 ml. molybdoferredoxin (1.5-2 mg protein) and 0-15 ml. azoferredoxin (1-1.5 mg protein). The final pH was 6.8. When an ATP-generating system was used, 55 μmole per ml. of acetyl phosphate was added. ATP:

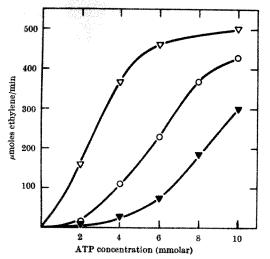

Fig. 1. Effect of ATP concentration on the rate of acetylene reduction catalysed by molyhdoferredoxin and azoferredoxin at different levels of ADP.

∇, ATP alone; O, ATP + ADP (3 mmolar); ▼, ATP + ADP (5 mmolar).

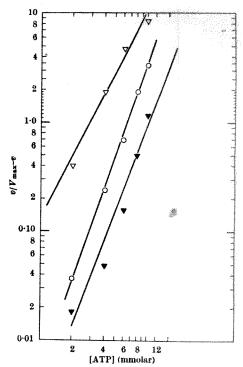

Fig. 2. A plot of log ATP concentration against log $(v_i V_{max}, v)$ at different levels of ADP when molybdoferredoxin and azoferredoxin were used to catalyse the reduction of actylene to ethylene in the presence of sodium dithionite. ∇ , ATP alone; \bigcirc , ATP + ADP (3 mmolar); \bigvee , ATP + ADP (5 mmolar).

acetate phosphotransferase was already present in the extract used. The gas phase was 0.85 atm. hydrogen and 0.15 atm. acetylene.

Early in this work when crude extracts were used, we found that ATP would support acetylene reduction in the absence of an ATP generating system. Neither ADP nor GTP would function in place of ATP. With the generating system the optimum ratio of magnesium ions to ATP was 2.5:1, but with ATP alone the optimum ratio of added magnesium ions (9 mmolar) to ATP (18 mmolar) was 0.5. The 0.5 ml. of crude extract used contained up to $2.4 \mu \text{mole}$ of magnesium ions (1.2 mmolar in the reaction mixture), all of which appeared to be bound to proteins for no activity was observed unless magnesium ions were added. The optimum ratio of magnesium ions to ATP when partially purified molybdoferredoxin and azoferredoxin were used was 0.5. At this ratio the initial rate of acetylene reduction catalysed by partially purified molybdoferredoxin and azoferredoxin (using sedium dithionite as an electron donor) was affected by the concentration of ATP (Fig. 1). A Hill plot** of log $(v/V_{\rm max}-v)$ as a function of log ATP concentration gave a straight line with a slope of about 1.9 (Fig. 2) suggesting that two molecules of ATP participate in the rate determining step or steps of the reaction catalysed by the acetylene reducing system. When crude extracts were used in these experiments in conditions where ATP was hydrolysed at a fast rate to ADP, slopes higher than 2 were obtained. These results were caused by ADP inhibition which will be shown later in this communication.

When a substrate quantity of ATP (18 mmolar) was used in place of small amounts of ATP (0.2 mmolar) and an ATP generating system, crude nitrogen fixing extracts catalysed a linear rate of reduction of acetylene, but the reaction stopped after 10-15 min although ATP was still

Table 1. EFFECT OF ADP AND AMP ON THE RATE OF ACETYLENE REDUCTION BY EXTRACTS FROM Clostridium pasteurianum

Addition	Percentage inhibiti
ADP, 3 mmolar	42
ADP, 5 ,,	53
AMP, 5	51

ATP concentration was 18 mmolar.

present. In contrast, using the ATP generating system the reaction continued linearly until all the ATP generator was consumed. ATP at the concentration used (18 mmolar) was not itself the cause of the decrease in reaction rate, for it was found that substrate concentrations of ATP in the presence of ATP generating system resulted in acetylene reduction at a rate close to that obtained when catalytic amounts of ATP and the ATP generating system were used.

The early decline in the rate of acetylene reduction when substrate quantities of ATP were used was simultaneous with the rapid disappearance of ATP even in the absence of acetylene, and this suggested that a product or products of ATP utilization were inhibiting the reaction. This was further indicated by experiments in which the crude extract was incubated in the presence of magnesium ions and ATP for 20 min before the acetylene was added. In these conditions, no reduction of acetylene occurred unless additional ATP or ATP and acetyl phosphate were added. When, however, ATP was added after the 20 min preincubation with ATP, the rate of acetylene reduction was much less than if ATP has been added initially.

The products of ATP utilization, ADP and AMP (unpublished results of Kennedy and Mortenson), produced by crude extracts during reduction of acetylene were shown to inhibit acetylene reduction (Table 1). When partially purified molybdoferredoxin and azoferredoxin4 substituted for the crude extract and sodium dithionite was used as the electron source in place of reduced ferredoxin, ADP but not AMP inhibited acetylene reduction. The result with AMP suggests that the inhibition of acetylene reduction by AMP when crude extracts were used was probably caused by the presence of adeny-

late kinase.

The effect of the concentration of ATP on the rate of acetylene reduction catalysed by partially purified molybdoferredoxin and azoferredoxin4 with dithionite as an electron source was examined at 3 and 5 mmolar ADP. The results were plotted as log $(v/V_{\text{max}}-v)$ against log ATP concentration 5,6 (Fig. 2) and the slope of the straight line obtained with both 3 and 5 mmolar ADP was about 3. With 5 mmolar ADP the line was shifted to the right which suggested that ADP, the product of ATP utilization in the nitrogen fixing system (unpublished results of Kennedy and Mortenson), may regulate the acetylene reducing system by functioning as a negative modifier. When the ratio of ATP to ADP is high as shown here with an ATP generating system, no ADP accumulates and acetylene reduction is optimal. When the ratio of ATP to ADP is low, acetylene reduction (nitrogen fixation) is inhibited and the ATP remaining can be used for more critical cell functions.

These studies were carried out using acetylene reduction as a measure of nitrogen fixation because of the ease and reliability of measurement of ethylene. This seems to be valid because all data indicate that the mechanisms of reduction of nitrogen and acetylene are similar1,2.

Inhibition of Multiplication of Foot and Mouth Disease Virus in Adult Mice pretreated with Freund's Complete **Adjuvant**

Increased resistance has been reported in certain virus infections after stimulation of the reticulo-endothelial system (RES)1,2. We have observed that, in adult mice pretreated with complete Freund's adjuvant3, the multiplication of foot and mouth disease virus (FMDV) is inhibited4, and we report here the results of further

experiments.

Two attenuated strains of FMDV, type "O", were used. One was lethal and the other non-lethal to adult mice. The non-lethal strain induces a symptomless but regular virus multiplication in the pancreas, accompanied by viraemia, after intraperitoneal inoculation of a hundred suckling mice half lethal doses $(smLD_{50})$ (ref. 5). All suckling and adult mice were from an inbred colony of the Balb/c strain, susceptible to experimental infection with FMDV. Suckling mice were used for virus titrations, serum neutralization tests and for detection of viraemia. Adult male mice, 8 weeks old, were used for comparative study of virus multiplication. Freund's complete adjuvant containing standard amounts of desiccated cultures of Mycobacterium tuberculosis (5 mg/20 ml. of adjuvant) was prepared by the classical method3. Pretreatment with adjuvant consisted of intradermal injections at four sites, giving a total of 0.3 ml. to each mouse. The first set of injections were given 10 days and the second set 3 days before inoculation of virus. Bordetella pertussis, when used to induce the adjuvant effect, was in the form of formolized vaccine, available from the Institut Pasteur, In each experiment, thirty adult mice in ten groups served as controls and an equal number in the group pretreated with adjuvant. Virus multiplication was studied comparatively by assaying virus titres in the pancreas and testing for viraemia. For virus assay, at each post-inoculation time, mice from the control and pretreated groups were killed at intervals for virus assay. To test for viraemia all mice were bled from the orbital vein. The blood, diluted 1:10 in Earle's tissue culture medium without anti-coagulant, was tested immediately. Serum virus neutralization tests were performed on pooled samples of sera from control and pretreated mice, keeping the quantity of virus constant. The titrations of the interferon-like substance were carried out in an L cell-vesicular stomatitis virus system. The interferonlike substance is referred to as interferon in the text chiefly because of two characters: this virus inhibitor is acido-resistant (exposed to $p \to 2 \cdot 0$ for 72 h) and is active in cells of mouse origin (L cells) while inactive in cells from other species. The interferon titres reported in Fig. 2 are obtained from extracts of spleen and are expressed as reciprocals of the dilution capable of reducing the number of plaques (unit of interferon) as compared with control cultures by 50 per cent6.

Table 1, which summarizes the results of three experiments, shows that 65 per cent of pretreated mice showed no viraemia compared with 100 per cent positive results with controls. The 35 per cent of mice which were positive in the pretreated groups showed lower virus titres in the pancreas than did controls. Furthermore, these titres appeared later and disappeared earlier. With a variable virus inoculum, it was observed that in controls only $50 \ smLD_{50}$ was required to induce viraemia in $50 \ per \ cent$ of mice, while in pretreated mice 700 $smLD_{50}$ was required to induce the same effect. Inhibited virus multiplication was observed even with the lethal strain of virus. In this case, while in controls the LD_{50} for adult miceexpressed in smLD₅₀—was less than 5 smLD₅₀, in mice pretreated with adjuvant it was 300 smLD₅₀. Similar protection was observed in mice which had been pretreated with B. pertussis (twice before the inoculation of virus as in the case of Freund's adjuvant). To test whether M. tuberculosis incorporated into Freund's adjuvant was responsible for inducing the inhibition of virus multiplication, the effect of pretreatment with incomplete Freund's adjuvant was examined. In this case, no virus inhibition was noticed. Wax D (ref. 7) fractions from human strains of M. tuberculosis which contain the peptide moiety' have been shown to be capable of inducing increased immunological response. To test whether some of these fractions could inhibit virus multiplication, mice were pretreated with adjuvants containing waxes $D_{p_{15}}$ and D_s from strain Canetti. Only wax $D_{p_{15}}$, which contains the peptide moiety, could inhibit virus multiplication, while the wax D_s , which has no peptide in it, failed to do so.

Table 1. TITRES OF FOOT AND MOUTH DISEASE VIRUS IN PANCREAS AND PERCENTAGE OF MICE SHOWING VIRAEMIA IN ADJUVANT PRETREATED AND CONTROL MICE

Post-	Control m	ice groups	Adjuvant pretreated mice groups		
inoculation	Virus titres Viraemia		Virus titres	Viraemia per cent	
time (h)	in pancreas	in pancreas per cent			
6	103	0/30 0	10 ^a	0/30 0	
16	10*	4/27 15	10 ²	0/27 0	
24	10***	16/24 65	10 ^s	1/24 5	
36	10***	21/21 100	104	3/21 15	
48	10***	18/18 100	102	6/18 35	
64	104.0	13/15 85	102	0/15 0	
72	10***	10/12 80	$\tilde{10^2}$	0/12 0	
96	102	1/9 10	102	0/9 0	

The titres in pancreas are expressed in suckling mice LD_{50} . Viraemia is shown with the numerator indicating mice which were positive and the denominator shows total mice tested.

The titres below 10^{5} g of pancreatic tissue cannot be detected and so are considered as the lower detection limit.

All the mice were injected intraperitoneally with 100 suckling mice LD_{50} of foot and mouth disease virus at zero time.

The two most important factors responsible for restricting virus multiplication in vivo are antibodies and interferon8. Comparison of antibody concentrations in control and pretreated mice is shown in Fig. 1. Clearly, in the controls antibodies could be detected after the fifth day and reached 2×104 infectious dose neutralizing antibodies (abs)/ml. of serum on the seventh day and continued to show similar titres until the sixth week. In mice pretreated with adjuvant, the antibodies appeared later (by or after 7 days) and, although by the third week they had reached the same titres as in the controls, they disappeared by the tenth week when in the controls there was still a titre of 2×10^3 abs/ml. of serum.

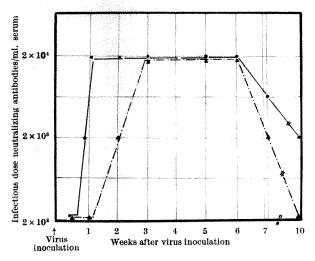

Fig. 1. Comparative antibody concentrations in pretreated and control mice. All mice were injected with 100 suckling mice LD_{50} of foot and mouth disease virus at the same time and samples of sera were tested on pooled material from each group. These serum virus neutralization tests show that antibodies in controls (———) appear earlier and disappear later than those in pretreated mice (\blacktriangle —·— \blacktriangle).

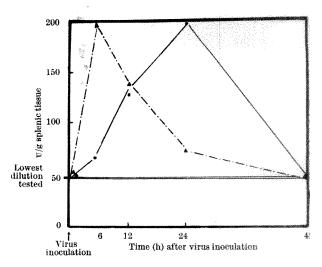

Fig. 2. Comparative concentration of interferon in pretreated and control mice. All mice were injected intraperitoneally with 100 suckling mice LD_{10} of foot and mouth disease virus. In mice pretreated with adjuvant, highest titres are observed at 6 h ($\Delta - \cdot - \cdot \Delta$); in controls ($\bullet - \cdot - \bullet$) these are seen only at 24 h.

The concentrations of interferon in mice treated wif adjuvant and in controls are shown in Fig. 2. No inte feron could be detected before virus had been inoculated either in pretreated or control mice. In pretreated mic highest titres were observed at 6 h with a progressive decline at 12 and 24 h. In controls, the opposite situatic obtained, with the lowest titres at 6 h reaching a max mum by 24 h. Concentrations of interferon decreased i less than the limit of detection in both groups by 48 h.

The experimental evidence indicates that substance with similar actions with respect to Freund's complet adjuvant can induce an effect, as a result of which virt multiplication is inhibited. The low concentrations of ant bodies in the pretreated group preclude the possibility antibodies inhibiting the virus multiplication in the present system. On the contrary, the altered productic of interferon in the two groups seems to be important virus inhibition. These results resemble those of Youngas and Stinebring, who have shown that pretreatment wit BCG results in mice being hyper-reactive to the inte feron stimulating effect of E, coli endotoxin. The absent of interferon at zero hours (at the time of inoculation virus) suggests that interferon is produced under the stimulus of the inoculated virus. In view of the previous observations that it takes at least 4 h to complete or virus multiplication cycle in FMDV, the high titres interferon, as early as 6 h after inoculation of viru followed by a progressive decrease, suggest that, in min pretreated with adjuvant, interferon is produced befor or in the initial stage of virus multiplication while controls it follows the multiplication.

The increased immunological response reported prev ously 10-12 and early production of interferon observe here suggest the possibility that these apparently differen reactions are a manifestation of enhanced functions the same set of cells, mobilized and activated by Freund After such treatment every function of the adiuvant. reticulo-endothelial system can be expected to be stime lated and the answer, evident from the response, depend only on the nature of the foreign substance injectedfor example, antigen-like human serum albumin¹¹ provoks production of antibody while the virus provokes ear production of interferon. It is interesting that there increasing evidence of the role of the reticulo-endothelia system, particularly spleen and macrophages 13-17, the production of interferon.

I thank the Institut National de la Recherche Agron mique for a senior research fellowship and the Wellcon Research Foundation for a travel grant. I also than Dr A. Paraf for advice, Dr De Maeyer for accepting th interferon titrations in the initial stage of investigation and Dr Jollès for purified wax D fractions.

GENETICS

Lactose Intolerance in Asians

This investigation was prompted by the clinical observation of lactose intolerance in five Asian students who were attending a gastroenterological out-patient department for vague abdominal pain associated with intermittent diarrhoea. Lactose intolerance is now a well recognized clinical entity, being more common in asymptomatic negroes1,2 and Australian aborigines3 than in Caucasians.

This initial investigation was carried out to determine the incidence of lactose intolerance in a group of asymptomatic Asian students. The control subjects were twelve asymptomatic Australian students of Caucasian background. The test subjects were twenty Asian students. Fifteen were Chinese from Hong Kong, Singapore or Malaysia, and five were from the Indian sub-continent. All were free of symptoms but many on specific questioning admitted to abdominal pain and diarrhoea after ingesting milk. To test for lactose tolerance, 80 g of lactose dissolved in water was given to fasting control and test subjects. Blood samples were taken after 0, 30, 60, 90 and 120 min. Total blood sugar reducing substances were determined by a "ferricyanide" method adapted to the autoanalyser. Any symptoms stated were noted. To test for glucose-galactose tolerance, the same procedure was repeated with both groups after the oral administration of 40 g each of glucose and galactose.

In the control group the mean maximum increase in blood sugar after 80 g of lactose was 34 mg per cent with a range of 20-50 mg per cent. After 40 g of glucose and galactose the mean maximum rise was 43 mg per cent

with a range of 20-105 mg per cent. In Chinese students, the mean maximum increase in blood sugar after 80 g of lactose was 8 mg per cent with a range of 0-25 mg per cent. In the Indian students, the mean maximum rise in blood sugar was 8 mg per cent with a range of 0-30 mg per cent. After 40 g each of glucose and galactose the Chinese students showed a mean maximum increase of 46 mg per cent with a range of 30-65 mg per cent; the Indian students had a mean maximum rise of 32 mg per cent with a range 20-45 mg per cent. These results are set out in Table 1. The mean results of the blood sugar estimations in the different racial groups are shown graphically in Fig. 1.

Abdominal pain and diarrhoea were experienced by patients 5 and 9 of the control group. All patients in the Chinese group and all except patient 5 in the Indian group complained of abdominal pain, borborygmi and diarrhoea.

This study of asymptomatic volunteers demonstrates that intolerance to lactose is common in a Chinese and Indian student population. It is accepted that an increase in blood sugar of less than 20 mg per cent after a loading dose of more than 50 g of lactose is associated with intestinal lactase deficiency4. Figures between 20 and 25 mg are equivocal. All Chinese developed abdominal pain and diarrhoea after lactose ingestion. This was associated with a mean increase in blood sugar of 8 mg per cent compared with a mean increase of 34 mg per cent in the control series. No Chinese experienced any symptoms after the glucose-galactose test and here the mean increase was 46 mg per cent compared with a mean rise of 43 mg per cent in the control series. Four out of five Indians experience abdominal pain and diarrhoea after ingesting lactose and this was associated with a flat lactose curve. The fifth patient (patient 32) experienced no symptoms after ingesting lactose and had a maximum rise of blood sugar of 30 mg per cent.

It is interesting that this patient has been resident in Australia for 13 yr and this in itself would argue that the

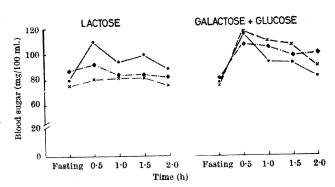

Fig. 1. Mean obtained for blood sugar values in lactose and glucose galactose tolerance tests in Caucasian ($lue{---}$), Chinese ($\times --- \times$) an Indian ($lue{---}$) subjects.

lactose intolerance common in Chinese and Indians may have an acquired rather than a genetic basis. In addition, the incidence of this enzyme deficiency seems to be too

high to be explained by a recurrent mutation.

This work has two implications. First, lactose intolerance should always be considered in Asian patients complaining of abdominal pain and diarrhoea. Second, it has a much wider socio-economic application when the part played by milk and milk products in food aid programmes to under-developed Asian countries is considered. It could be that aid in this form with the subsequent induction of diarrhoea is not the most efficient method of helping a malnourished community.

We thank Dr R. Bartholemew for carrying out the blood sugar estimations. We also thank Professor R. B. Blacket and Professor R. J. Walsh for their encourage-

APPLIED SCIENCE

Combustion of Coal in Oxygen

DURING an investigation of high temperature flames (at more than 2,500° K), we have developed a burner system capable of burning up to 6 g/sec (50 lb./h) of coal in oxygen to form a stable, continuous flame. An integral part of this development has been a study of the mechanisms which control the rate of combustion.

A detailed account of the burner system is given elsewhere but, essentially, the coal was fed by a screw into a mixing device and then into the burner head. stabilization was achieved within the burner head by means of a water-cooled bluff-body and combustion took place at atmospheric pressure in a zirconia tunnel.

Coal (4 per cent ash, 38 per cent volatile matter) was ground and graded according to size by sieving and centrifugal classification in air to produce seven fractions in an overall size range of 12-70µ. Each fraction contained more than 50 per cent by weight within a 10µ interval. Flame temperatures were measured by the line reversal method which indicated a variation in temperature along the length of the flame from 2,900° to 3,050° K. At this temperature we concluded that the reaction temperature remained sensibly constant along most of the flame

Each size fraction was burned at two ratios of oxygen to carbon: (a) with oxygen just less than stoichiometric for water and carbon dioxide production (assuming no dissociation), that is, a ratio of oxygen to carbon atoms of 2.11; and (b) at a ratio of 1.51. Burning times for the various fractions were compared on the basis of the distances from the burner head necessary for 80 per cent by weight of the coal to be burned. The extent of com-bustion was determined by means of a water-cooled sampling probe in which not less than 50 mg of solid material was collected during a flame immersion time of 30 sec. Burning times were calculated from these measured distances and calculated values of the particle velocities. Calculation of the velocities was based on the assumption that the particle velocity was the same as the gas velocity and the latter was obtained from measured values of the

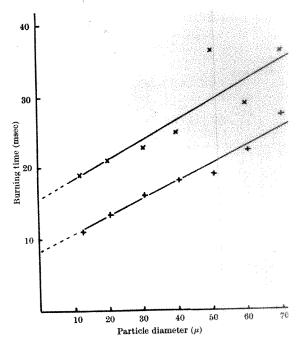

Fig. 1. Effect of particle size on burning times. × , (ratio, 1.51; +, oxygen-carbon ratio, 2.11. Oxygen-ca

mass flow rate of combustion products, flame dimenflame temperatures and the computed composition (products2. The burning time versus particle dia for both oxygen-carbon ratios is plotted in Fig. 1 two conclusions have been drawn from these data.

First, over the particle size range of 12-70μ, the bu times of coal particles in oxygen which give 80 per combustion can be described by the empirical equati

 $t = 2.8 d + 16 \times 10^{-3}$ (oxygen-carbon ratio of 1.51) $t = 2.4 d + 9 \times 10^{-3}$ (oxygen-carbon ratio of 2.11)

where t is the burning time in sec and d is the equi-

spherical particle diameter in cm.

Second, departures from the first approximation linear dependence of burning time on diameter have explained in terms of the type of mechanism exerts the predominant effect on the burning Between 12 and about 30µ the data were satisfax correlated by means of linear relationships, w between 30 and 70µ better correlation was obtained it was assumed that the burning time was propor to the square of the diameter. For single pa greater than 80µ in diameter, it has been demonst that mass transfer processes control the rate of co tion. As the particle size is reduced, a critical si be reached when chemical processes begin to) significant part in determining combustion rates. basis that the time of burning is proportional square of the particle size when mass transfer propredominate and proportional to particle size chemical processes exert the greater influence on th of combustion, it is suggested that, in the conditi these experiments, the critical size lies in the vice 30µ.

5. 1, lubricant migration, ecause of surface leakage nould not occur because, loop by surface leakage vould require an increase uld increase the pressure the creep. This method s evidently been over-

by transfer in the vapour is sufficient, however, to ner such that the desired hat location where the urface, and therefore a fer by creep and through 78 return the lubricant to this location. A capillary lubricated bearing with this property was constructed and is shown in Fig. 2. The moving element was a tube 0.710 cm outside diameter and 0.710 cm long bored out to leave sharp edges at the ends. It was made of hardened AISI 410 ferritic stainless steel and weighed 270 mg. The displacement of the moving element was 0.280 ml. so that it could be hydrostatically floated by adjusting the liquid density. It ran in a glass tube with a bore of 0.760 cm. The glass tube was filled with a water-isopropanol mixture, which would float the steel ring best, and then sealed. The moving element was free to rotate, and behaved like a compass; it was also free to translate and made a sensitive level. The liquid always returned to the crevice of this bearing and re-centralized the moving element after shocks had sprayed the liquid randomly within the tube.

Hydrostatic support can stabilize, at most, three degrees of freedom of a moving element, the other three degrees of freedom being gravitationally equipotential. In the bearing of Fig. 2, capillary centralizing forces operate in two rotational and two translational degrees of freedom. The vertical degree of freedom is strongly biased hydrostatically because the capillary forces alone could not support the weight of 270 mg. Non-contacting and therefore stiction-free supporting forces could also be obtained electrostatically or magnetically4,5, and the necessary centralizing forces obtained without power dissipation by capillarity.

Fig. 2. A capillary lubricated bearing. The moving element is a tube, running in a sealed glass tube. With this configuration the lubricant has a minimum surface energy.

10 mm

In conclusion, capillary forces can centralize the moving element of a bearing. Such bearings can be arranged so that the liquid lubricant is stably retained against creep and vapour transfer. Steady loads can be supported hydrostatically while capillary forces centralize the moving element stiction-free and out of contact with solid supports.

BOOK REVIEWS

HOW MEMORY WORKS

Mechanisms of Memory

By E. Roy John. Pp. xii+468. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 112s.

This is probably the first book that provides a full scale survey of the mechanism for the storage of information in the nervous system and in this sense it is a landmark of historical importance. It provides a useful review of the literature, with reasonably sophisticated ideas about the nature of the representation of information in neural populations. For all this we can be most grateful to Dr John, as also for his own contributions to several aspects of the subject. Unfortunately, although there is some caution and reservation in discussing published work, this does not go far enough. In many parts of the book we are referred to unpublished work, personal communications and ephemeral publications such as the Federation Proceedings. The subject still lacks a firm body of well established anatomical, physiological and biochemical facts. Many of the results alleged by various authors are probably wrong. The author does not always examine them and assess their weakness or strength, but uses a process like algebraic summation to arrive at a probable answer for contradictory results. This reservation does not alter the fact that this is a most exciting book on a subject of very great current interest.

The author's review wisely involves no attempt to survey the vast behavioural literature on learning and forgetting. Instead his purpose is clearly set out as "to present and discuss some of the facts and logical considerations which may guide our strategy in devising experimental approaches to the problem of the physical basis of memory". He lists four fundamental functions that a memory mechanism must perform: (1) The configuration of external and internal stimuli impinging on an organism, which constitute experience, must somehow be coded into a neural representation. (2) This must be stored. (3) There must be access to specific stored items. (4) "The retrieved data must again be decoded into neural activity, which somehow revives . . . the original experience and thus constitutes a memory".

Even this abbreviated paraphrase will indicate the magnitude of the problems to be attacked. He proposes to include the phenomena of human memory, but since his purpose is to deal with the physical basis his account is inevitably largely of animal experiment. He first deals briefly with the problem of localization, leading him to "question the validity of connectionist theories according to which memory must be localized in a region". This section consists only of a short review of mainly classical attitudes to the problem. Lashley and Kluver are expounded but not criticized. Neither Penfield nor Weiskrantz is mentioned. Indeed, we should not expect to find them, as the "behavioural literature" is to be omitted, but in discussion of this topic the omission is grievous. Of course, the difficulties of "connexionist" theories are well recognized. No one supposes that memory is stored in specific cells so isolated that "if they were to discharge due to spontaneous causes, we would expect to be continually bombarded by unrelated frag-ments of recollections". The problem surely is how whatever changes take place in cells are so related as to provide the necessary neural representation.

In the author's statistical hypothesis "the information

. . . from the activity of a group of cells (is) repres by the orderly behaviour of the ensemble, compared the random or characteristic basal discharge pa The information content of the ensemble might a of the emergence of organized patterns of reference random or rhythmic baselines".

In any case, as he puts it, "whether memory is a in a place or a process in a population . . . the sus change . . . must be mediated by some alterat matter". To find more about this change he first dis the "labile phase in memory" during which consolir is taking place—the vulnerable stage, varying from seconds to days or weeks. There is here a valuable sion of the possibilities of reverberatory activity as various difficulties in supposing that it could ca representation. This and the work with spreading c sion leads him to the conclusion that intermediate h mechanisms of two sorts may exist.

Passing to discussion of the mechanism of stable mation storage, he first reviews the evidence tha mediated by the "structure of macromolecules" a particular RNA. He and his colleagues have rej and claim to have confirmed the experiments of McC with planarians. As he points out, however, the of Hartry et al. suggest that cannibalism alone faci learning. After describing the experiments on the of inhibition of protein synthesis on learning he con that although the experimental results are not com-"there is an impressive quantity of data strongly pe towards RNA and protein synthesis as deeply impl in the function of memory".

Basing himself on this probability, he proceeds: cuss theories as to the means by which afferent produces changes; for example, by what Robinson in work not yet published) calls pattern neurones dis ing pattern molecules into an extracellular space (cell?) nearby, where they form a storage unit which with time by formation of co-molecules. Retric obtained by release of pattern molecules from the act neurones and their recognition by the storage uni John recognizes that such hypotheses are so gene to be quite unsatisfactory and indeed a waste of t

the present state of knowledge.

The following sections return to the question of lo tion and the results of ablation experiments, and t again much exposition of Lashley and Hebb but wit critical discussion of more recent work. This is p the least original part of the book. Indeed, the au clearly not at home in the discussion of brain I He falls into the trap of using the word "function" out considering what it means. Lashley himself w immune from this, which indeed is difficult to a one starts to talk about tests for "the localization function". A major objective of experiment sho to try to discover what we do mean by "functions brain". What does John suggest instead? All he ca is "intuitive contradiction of the notion that the n of the response is localized in a discrete mediating re-

When Dr John proceeds to the relation of brain. tials to memory we feel that he returns to ground congenial to him. A review of the various el phenomena that can be observed in the brain is pa and will be useful for those not familiar with the himself has produced data on the distribution of el changes in the various phases of learning. Microel studies lead him back to the problem of whether discharge of a single neuron . . . might be suffice represent a particular item of information". cludes that it could not, in spite of Hubel and because of the lability of response of any given cell possibility of conditioning, as shown by Morell and His conclusion is that "characteristic modes of

tion, reflecting temporal patterns of average active are established during learning". To validate returns to experiments of the type he has studied s

rate to elicit 'labelled responses' with the same frequency in various parts of the brain". These sections contain much documentation to show that specific modes of activity emerge during conditioning throughout extensive parts of the brain and, furthermore, that an animal can learn to differentiate between two temporal patterns of activity applied to the cortex. There is undoubtedly much of interest here, but it is difficult to extract enough detail to be convinced of all that is claimed.

In short the author's wide review and interests make this an interesting book. His ideas for experiments on various aspects of the subject are stimulating, but many of the results have been only imperfectly reported in scattered and brief papers. The present work does not succeed in providing the missing data that will show us either the place of RNA or the significance of changes of patterns of electrical potential during learning. Nevertheless, we can be grateful to Dr John for his courage as one of the first to venture into many aspects of the subject.

J. Z. Young

ADVANCES IN TERATOLOGY

Advances in Teratology

Edited by D. H. M. Woollam. Vol. 2. Pp. 306. (London: Logos Press, Ltd., in association with Elek Books, Ltd., 1967. Distributed by Academic Press, New York and London.) 84s.

Until recently the history of the development of a scientific status for teratology, especially in man, has been a chequered one. Indeed, I can remember criticism of a distinguished physician who, in an examination with which he was concerned, set a question on the embryological origin and possible cause of a not uncommon foetal abnormality—coarctation of the aorta. Even the experimental evidence adduced by, among others, Giroud of Paris and the late Dr James Millen (in conjunction with the editor of the volume under review) and indicating the teratogenic influence of vitamin imbalance, received little general recognition. In the present decade, however, largely as a by-product of the tragic demonstration of the adverse effects on development of thalidomide. there has been an enormous increase in interest in the nature and causes of foetal abnormality. The subject of teratology is now accepted as one with a distinct status in biology and recognized to have considerable practical significance; the development of interest in it has been such that the publication of an annual volume on Advances in Teratology is now possible. Dr D. H. M. Woollam was asked to assume the responsibilities of the editorship of the series. As a colleague and friend of his, it is not really for me to assess his editorial work. I may, however, be permitted to write that, in my opinion, he has carried out his duties with discretion. In particular he has successfully persuaded a distinguished group of investigators to discuss specialized aspects of the current literature on teratology and teratogenesis in the light of their own studies in the fields concerned.

Of special interest in the volume under review is the contribution by the late Sir Denis Browne. As a paediatric surgeon at the Hospital for Sick Children, Great Ormond Street, who had to deal with many forms of bone and joint abnormality commonly found in human neonates and young infants, for many years he had stressed a mechanistic interpretation of the aetiology of certain of these malformations (for example, inverted feet, extended knees, dislocation of the hip, forms of scoliosis and torticollis). Browne was a skilled and very experienced photographer of clinical material, and the presentation of his views is accompanied by a large number of photographic illustrations of the conditions considered. There can be no doubt that his interpretations of a number of the

graphs. Nevertheless, most interested parties will probably continue to regard his specimens as falling within a group of deformations rather than malformations, but it was important that an authoritative expression of his views should have been made available. Browne took his personal, and often heterodox, views on malformations very seriously. He was fearless in presenting them, and his essentially clinical attitude to the problems discussed made him impatient of results of animal experiments. But he was a fair fighter; and it was characteristic of the man that he should have included in his presentation the sentence from Spinoza: "I have laboured carefully not to mock, lament or execrate, but to understand".

Other papers included in the volume are on rubella and antibiotics as teratogens, intra-uterine growth retardation, homocystinuria, chromosomal studies of spontaneous abortion, and teratogenesis in inbred strains of mice. Only special interest or personal taste can easily distinguish between their relative merits. All are authoritative and give good or excellent coverage to the literature concerned. There is also included a brief but useful account by Drs Cecilia Lutwak Mann and Mary F. Hay on the flat-mount blastocyst technique as applied to investigations of embryotrophic agents. Two of the contributions come from Britain, one from Italy; the remainder are products of American laboratories. second volume of Advances in Teratology is well up to the standard and level of interest of the first; it is very much to be hoped that the future will see the indefinite continuance of the series. The printing and illustrations are admirable. Unfortunately the price, though not excessive for these times, will make the volume for many a desideratum rather than a personal possession.

ALMOST ALL THE VIRUSES

The Molecular Biology of Viruses

(Proceedings of the Symposium held at the University of Alberta, June 27th to 30th, 1966, in conjunction with the Faculty of Medicine of the University of Alberta.) Edited by John S. Colter and William Paranchych. Pp. xvi+730. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 156s.

Nowadays the proceedings of almost every major international meeting are eventually published as a book. This is only as it should be, of course, because only a very small proportion of the world's scientists working in any particular field have the opportunity of actually going to meetings which interest them. Unfortunately, however, the inevitable delays in publication are usually so long that by the time the book appears everyone has heard what was said at second hand and, anyway, all the important new information has usually been published in the journals.

This book is no exception. It has taken the editors, who have a thankless task, and the publishers 15 long months to collect together and publish the thirty-six papers, and the discussions, given in June 1966 at the symposium on the molecular biology of viruses at Edmonton, Alberta. Almost all the material in this book is now available, less conveniently perhaps, elsewhere. None the less, the book will have its uses as a reference source and an archive. Collected together in one place are what boils down to a series of review articles of the ideas on various aspects of the molecular biology of bacterial and mammalian viruses that were current in 1966.

The symposium would have been better called North American rather than International. Only ten of the ninety-one authors work in Europe, and the rest of the world is unrepresented. But this does not matter all that much because most of the chief American groups, which so dominate the field, provided contributions. Perhaps the

most notable absentce was Professor Spiegelman who, although scheduled on the programme of the symposium to give a paper on the replication of Q3, was unwell at the time. Consequently, the section in the book on RNA bacteriophages gives few hints of the aerimonious dispute, on whether or not RNA bacteriophage replication involves a minus strand, which was raging between Spiegelman and almost everyone else, but Weissmann in particular. Those who went to the meeting were spared a repetition of the sparring match which took place at the Gordon Conference a week before the Edmonton Symposium and it is a great pity that the book contains none of this. For, after all, the main role of this book is as an archive and in the summer of 1966 the problem of RNA phage replication was one of the hottest topics in virology. Now, of course, Spiegelman has convinced himself that minus strands do exist while Weissmann, whose article in the book describes the role of replicative form and intermediate, has now gone on to question whether these structures really exist in vivo. All this goes to show just how out of date this section of the book is.

But it would be wrong to give the impression that the book is principally concerned with RNA bacteriophages. In fact, the symposium was ambitious enough to try to cover all the viruses with the exception of higher plant viruses. There are eight sections and only one of these is devoted to RNA bacteriophages. Three are on other bacteriophages, and there are sections on RNA and DNA mammalian viruses and two on oncogenic viruses. All these contain valuable reviews by leading workers. There is, just to take one example, a valuable paper by Brinton, who publishes less often than most, on his work on male specific F pili.

If I remember correctly, discussions of the papers at the symposium were quite extensive. They must have been severely edited or else the participants must have subsequently decided not to publish their remarks, because in the book there is never more than a page and a half of discussion after each section, which is a great pity.

A collection of review articles, such as this, is always valuable and this book is bound to find a place on library shelves if nowhere else. No doubt Academic Press had this in mind when they fixed the very high price which offectively excludes most individuals from the market.

JOHN TOOZE

LABORATORY ANIMALS

Husbandry of Laboratory Animals

(Proceedings of the Third International Symposium organized by the International Committee on Laboratory Animals.) Edited by M. L. Conalty. Pp. xvi+650. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1967.) 150s.; \$28.

This is a very interesting volume, the Proceedings of the Third Symposium of the International Committee on Laboratory Animals, held in Dublin in September 1965, and should be required reading by all those who use laboratory animals. Its importance is that this volume presents some of the known factors in the whole animal environment and the effects of these on tests using laboratory animals.

At present the use of laboratory animals is entering a new phase; the established pathogen and germ-free colonies has made it possible to pay more attention to the effects of environment on the animal, and, with more interest in animal behaviour, the influence of caging on the experimental animal is now becoming apparent.

This volume is the result of forty-six contributions from fifteen countries and a further thirty-two participants in discussion, and the individual chapters are of varied interest, but show the growth, scope and limitations of our present knowledge of these topics.

The text is divided into six sections. Seed handling, production and organization, include on handling scorpions and snakes, also technic skin grafting in rats and rabbits and a description experiments to assess the environmental in the mice.

Section 2 on nutrition is a series of papers which what is known about the vitamin, trace elements and calorie requirements of laboratory annuals, work on diets for SPF and gorm-free annuals.

Section 3 on ecology and disease includes aspects of stress in animals, the influence of age on the development of spontaneous neodes the successful limitation of mouse virus infections use of a filter fitting over each mouse cage.

Section 5 on physiology and psychophysiology in laboratory animals and of social stimulation and reproductive physiology.

Section 6 on pharmacology and pharmacology includes a paper on environmental influences of the responses in laboratory animals and pharmacology (a new term) and some nutritional paradoxes. The is used to describe the effects of environmental actual drug action. There is an author index to relieve text and a subject index.

The main impressions given by this book at although little is really known about many of the earlier attempts to stand of that many of the earlier attempts to stand of the response of laboratory animals will have to be seen that is now possible to detect the influence of the ment on experiments with laboratory animals of the ment on experiments with laboratory animals of the ment of the

we must know more about this important top.

This is a most stimulating book, not least to the need to study the total environment of the mental animal in the assessment of biological to the editor and the International Committee on the Animals are to be congratulated.

M. C. LA ANIMAL INTERNATIONAL TOP INTERNATIONAL

FLORA OF TURKEY

Flora of Turkey and the East Aegean Islands
Edited by P. H. Davis. Assisted by J. t. 1966
M. J. E. Coode. Vol. 2. Pp. xii+581. 1940
Edinburgh University Press, 1967.) 1898.

THE second volume of this invaluable work the heels of the first with a promptitude what e. congratulations to the editor and his col >: ! Volume 2 closely resembles its predecessor · · · format, being admirably printed, and admirable. what sparingly, illustrated. The do Cando' sequence of families has been modified to accord with modern opinions, with the apetalous Ille 19 Polygonaceae, Chenopodiaceae and Amarantae immediately after Caryophyllaceae, and for larger, and fairly obvious, alliance of Centralia Few will wish to argue with this departure, no v. re-unification of Hypericaceae and Guttiferac co much shaking of heads or shooting out of hip . sandwiching of Drosera between Frankenia and I' a little unexpected. For the rest, most of the control Malvaceae to a temporary stop at Celastraceae familiar to students of the Flora Orientalis, the wonders why the sequence has been altered to the Rhamnaceae and Celastraceae, and why Anacon has been interposed between these two sim 1. The permutations of phylogeny inscrutable, but the attitude of the Flora toward genera and species is on the whole so restreined to

mannered that an occasional demonstration of indi-

viduality is forgivable.

The decision to omit such internal geographical subdivisions as Mysia, Pisidia and Lycaonia will not be regretted, for this classical hangover was always something of a burden on our memories and a cause of confusion. It would, however, be useful to have some general indication of distribution within Turkey, apart from the grid and vilayet references, and it is to be hoped that some acceptable system will be devised in time for the next volume. R. D. MEIKLE

DESIGN IN FISHES

Functional Design in Fishes

By R. McN. Alexander. (Hutchinson University Library.) Pp. 160. (London: Hutchinson and Co. (Publishers), Ltd., 1967.) 10s. 6d. paper.

This book is about the structure of fishes. The functional design, as shown by the anatomical and physiological characteristics selected by the author, is related to evolu-tion by natural selection. Where appropriate the author supports his arguments with mathematics and physics, but, wisely, he warns the student that the subject must be approached in the manner of historians and critics. Mathematics and physics do not render the conclusions unassailable, because in any biological situation there are so many interacting structures and functions that there is always a danger of overlooking an important point.

The first chapter is about the coefficient of selection. The author examines the case of a genotype which increases the amount of food a fish obtains, or decreases energy consumption, thereby tending to increase the number of eggs laid by females, and being favoured by selection. He concludes that evolution by natural selection offers a plausible explanation for adaptations which result in small savings of energy.

The next five chapters deal with swimming, buoyancy, respiration, feeding and some sense organs. In each of these chapters analyses of the structures and functions of the organ systems are made, and related to the natural history of the fishes discussed.

A final chapter is concerned with the interactions between different functions or consequences of a single structure. This chapter is a most important one, because of the danger of oversimplification in a mathematical and physical analysis of a biological complex. It is so important that it should have been at the beginning rather than at the end of the book.

An appendix gives an outline classification of the fishes. It goes down to the level of orders, except in the case of the Cypriniformes and Perciformes, where some sub-orders are given. This brief systematic section is useful for students.

The reference list gives seven books on fishes, and there are eighty-eight other references, not representing an exhaustive bibliography, but serving as an entry into the literature of the subject.

There are sixteen clearly drawn figures. A highly commendable feature of the book is the complete relevance and full discussion of these figures in the text.

The book is a good introduction to the concept of functional design in fishes. It will be helpful to undergraduate students, for whom the series of books is intended. It will also be useful to workers in other fields of biology because it is a lucid and concise account.

One fault must be noted. Throughout the book the fish are called by their generic names only. This procedure is adopted even when it is clear that one species is meant and not all representatives of the genus. It is surprising that such nomenclatural inexactitude should occur, and it is to be hoped that this will be corrected in JAMES C. CHUBB subsequent editions.

SOIL BIODYNAMICS MISMANAGED

Soil Fertility

A Biodynamical Approach. By F. W. Pauli. Pp. xi+204. (London: Adam Hilger, Ltd., 1967.) 50s. net.

THE idea of the soil as a biologically active environment is well accepted. The relationships between plants and soil conditions continue to provide fascinating studies and we still have much to learn, In the preface to this book Professor Flaig draws our attention to the fact that recent emphasis on inorganic ions for plant nutrition has led to neglect of work on humus. Paradoxically, soil organic matter is most studied in countries using most mineral fertilizers. Dr Pauli aims to remedy the shortcomings of work with fertilizers by considering the soil ecosystem as a whole and relating the results of research on soil organic matter using modern analytical techniques to the problems of improving soil fertility measured by increased crop production. If this aim is achieved, then, as Dr Pauli hopes, some profitable new approaches to problems in soil fertility should develop. Unfortunately, he fails in his effort and what is worse sometimes confuses his interpretation of present knowledge. We shall have to wait longer for the inspired synthetical approach the subject demands.

The book is divided into seven chapters of text varying in length from three to seventy-three pages. Following four short introductory chapters, most of the text is in the fifth chapter on humus and soil fertility (59 pages), the sixth chapter on analytical techniques (73 pages) and the seventh chapter on man's exploitation of soil biodynamics (19 pages). There are two pages of conclusions and a glossary, bibliography and index.

The book is written without references inserted in the text so that the reader does not know either to whom to attribute the various statements or how much of the book represents published work and how much is interpretation by the author. The list of books, theses and papers provides no clue. The author states that his bibliography does not claim to be exhaustive and he does not indicate his method of selection. The bibliography does not contain several books one might expect to find, and references to published work by several established workers are missing from the list of papers.

Dr Pauli omits the role of fungi in the breakdown of plant material and the synthesis of humus. Normally, in aerobic soils the initial attack is by fungi, and subsequent decomposition by fungi and/or bacteria depending on the soil conditions. In anaerobic soils, plant remains are decomposed only by bacteria with the accumulation of lignified residues as peat. Terminology is bad throughout; for example, Dr Pauli writes of "low-molecular humus" when presumably he means "humus of low-molecular weight compounds".

On page 35, he describes clay minerals, "Many of the clay minerals consist of cations co-ordinated with water, OH-, O- and other anions, some of which are excellent bridging ligands and give rise to amorphous and crystalline solid particles. The crystalline particles show disorder and other imperfections, and may have amorphous coatings. The large surfaces contain many groups, among which are oxygen and different kinds of hydroxyl groups which may dissociate, yielding negatively and positively charged surfaces. In addition, electrical charges arise as a result of ionic substitution inside the lattice." Dr Pauli's basic description of the structure of a clay mineral differs so much from the accepted idea of layer structures of clay minerals derived basically from two units (a) of four oxygens at the corners of a tetrahedron with a silicon ion in the centre, and (b) of six oxygens or hydroxyls at the corners of an octahedron with typically an aluminium or magnesium ion at the centre, and with charges arising within the crystal from isomorphous replacement and at the edges of crystals by discontinuity, that one wonders at the source of his description and his interpretation.

Describing humus in hot and dry regions, Pauli says (page 65), "During a normal year, the atmosphere in hot and dry lands takes up much more water evaporating from the soil surface and transpired by the plants than the amount of water which reaches the soil as precipitation." The normal laws of physics demand that water balance should be achieved so that, starting and finishing with the same moisture content in the soil, water falling as rain must equal that lost by evapotranspiration and drainage. Presumably Dr Pauli means that in hot, arid regions, potential evapotranspiration is much greater than rainfall. Many other similar points occur throughout the book.

The book is well produced (although the copy received for review lacked plates 2 and 3). The price appears somewhat high for the length of the text.

The subject matter is one that should stimulate ideas in soil fertility and one hopes that another may soon succeed where Dr Pauli has failed. J. K. R. GASSER

STUDIES IN BIOLOGY

The Body Fluids and Their Functions By Garth Chapman. (The Institute of Biology's Studies in Biology, No. 8.) Pp. 68. (London: Edward Arnold (Publishers), Ltd., 1967.) 12s. 6d.

Guts

The Form and Function of the Digestive System. By John Morton. (The Institute of Biology's Studies in Biology, No. 7.) Pp. 58. (London: Edward Arnold (Publishers), Ltd., 1967.) 12s. 6d. net.

Microecology

By J. L. Cloudsley-Thompson. (The Institute of Biology's Studies in Biology, No. 6.) Pp. 48+2 plates. (London: Edward Arnold (Publishers), Ltd., 1967.) 12s. 6d.

THE Institute of Biology's series "Studies in Biology" is for sixth-formers, their teachers and first-year undergraduates. It has, as its aim, the presentation of concise reviews of "limited biological topics in which recent progress has been most rapid and important". In this it reflects an essential need. The problem is not so much that changes in research and ideas in biology are rapid but that they are extremely variable. Inevitably a major breakthrough in one field can be paralleled by virtual inertia in another. In such circumstances the maintenance of up to date editions of large texts becomes a difficult and uneconomical task and small, limited texts have to be employed.

It is the intention of the series to provide accounts not only of topics but also of "the methods that have been employed in elucidating the problems with which they deal" and to provide "suggestions for practical work for the student which should form a sound scientific basis for his understanding". Presumably implicit in the fact that none of the books has an index is the idea that they should be read, as it were, in one mental breath without the need for the resuscitation of cross-reference. How do these three books match up to these aims?

The Body Fluids and Their Functions is a comprehensive review. In parts it is so full of information and, in particular, taxonomic references that I suspect for the average student the physiological wood will get lost in the trees of specific names. It is chiefly at the first part of the book that this criticism can be levelled. It really is hard going with a first paragraph virtually a page long. What follows, however, is of great value. There are excellent sections on the dynamics of circulation, transport mechanisms and the homeostatic properties of the body fluids which are splendid examples of how the aims of the series can be achieved. Methods of investigations are integrated smoothly into descriptions of topics and the wider context of the subject is clearly demonstrated. The relation

between physiology and ecology and, most important, the role of physical science and mathematics in biological study are well illustrated.

Guts is written in a lively and, at times, humorous style; a virtue indeed in a textbook. At the same time it loses nothing in academic quality. It is a tribute to the author that he manages to make a potentially dull subject interesting and provides an insight into what laymen (and we can include students among them) see as the biologist's eccentric fascination in rather disagreeable subjects.

The framework for the text is a functional classification: herbivores and omnivores, deposit feeders, carnivores, filter feeders and fluid feeders. Unfortunately, within each category we find a review of species which although illustrating the variety of digestive systems, sometimes results in a rather barren catalogue of information. Possibly, it would have been better to use fewer examples and for more attention to be given to the gut as a selective barrier between the organism and the environment, emphasizing its ecological significance on the one hand and the physical processes involved in its functioning on the other. Methods of investigation are referred to, but mainly in a short appendix on practical work. There is little that illustrates how the methods and outcomes of investigations are related.

Microecology is not so much a review of the subject as a practical guide. The author is clearly more interested in getting students to find out about microecology than in telling them about the findings of microecologists; not a bad thing, but the result is that the book is a marked contrast to the other two. The depth and standard of presentation are much more elementary and clearly it is a book that would be used at the beginning of a course. Students would still need a review of the subject in its broader sense at the end.

The author argues the case for an autecological approach and through his review of measurement techniques and, particularly, his account of the ecology of cryptozoic animals which makes up virtually half the book, demonstrates the valuable part microecology can play in practical ecology classes. A chapter on microclimate and faunal distribution, however, is extremely shallow and the treatment of major ecological topics such as diurnal rhythm and food chains is appropriate to classes below the sixth form. Possibly the greatest disappointment is that no consideration is given to the place of microecology in applied biology. Pests of stored food products, and the role of soil organisms in agricultural practices, are only two examples that might have given the subject real meaning to the student.

Of the three books, I would select Body Fluids and Their Functions as being nearest to the aims of the series. But they all deserve a place in a school biology library. And a final comment: I am sure it would be very useful for students if indexes were provided.

P. J. Kelly

ROOTS OF MODERN MEDICINE

Medicine at the Paris Hospital

1794-1848. By Erwin H. Ackerknecht. Pp. xiv+242. (Baltimore, Md.: The Johns Hopkins Press; London: Oxford University Press, 1967.) 72s. net.

THE present-day clinical approach to the patient originated with the Hippocratic physicians in fifth century Greece, and the interpretation of his disease on the basis of anatomy grew out of the Renaissance. The correlation, however, of these two, the findings in the living patient and those discovered in his body after death, did not receive widespread attention until the first decades of the nineteenth century. At this time the humoral pathology of the ancient Greeks was being replaced by morbid anatomy as an explanation of disease. Here then are the

exciting transition took place in the new French schools of health which were a product of the Revolution. That of Paris was by far the most significant, and in this excellent book Dr E. H. Ackerknecht, professor of the history of medicine in the University of Zürich, deals with its first 55 years, 1794 to 1848.

The period was dominated by brilliant men such as Bichat, the founder of histology, his teacher Pinel, systematizer of general medicine, great teacher and psychiatrist, Broussais, the creator of physiological medicine, Corvisart, the popularizer of percussion, Laennec, the inventor of the stethoscope, and many more. Ackerknecht discusses each of the principal contributors to this revolutionary era in clinical medicine, and his phenomenal knowledge of the subject, gained from almost twenty years experience, allows him to sketch with great skill their essential background; in so doing he captures the spirit that must have infused the hospitals of Paris at that time. Little wonder that students from all the world flocked to them to learn the new medicine from its distinguished practitioners. The main goal was to discover as much as possible about the patient in life and in death, and the new techniques that were introduced furthered this end. To this was added statistics which gave numerical order to the masses of data being accumulated. Just as important, therapeutics could now be objective, although on the whole treatment advanced the least; some would say it retrogressed owing to over-zealous therapists. Another feature of the period 1794 to 1848 was the closer association of medicine and surgery which was beneficial to both.

Professor Ackerknecht's book on the Paris school of the early nineteenth century is the first in English to describe this fundamentally important period. His ability allows of little criticism, and his book, engagingly illustrated by Daumier sketches and adequately documented and indexed, will be essential reading for anyone interested in the medicine, science or general history of the nineteenth century. EDWIN CLARKE

CHROMATOGRAPHY AGAIN

Advances in Chromatography

Vol. 4. Edited by J. Calvin Giddings and Roy A. Keller. Pp. xiv+380. (London: Edward Arnold (Publishers), Ltd.; New York: Marcel Dekker, Inc., 1967.) 130s. net. LIKE its predecessors, this volume contains interesting articles on a variety of topics; the greater part deals with gas chromatography, and the book is rather expensive.

The first article, by L. R. Snyder, attempts a systematic approach to the understanding and control of solute RF values on alumina and silica in thin layer chromatography. It is a praiseworthy clarification of a very complex subject. Steroid separation and analysis are next dealt with by R. Neher, who gives guidance on choice of chromatogram for particular steroid groups and useful advice for enhancing the efficiency of the methods discussed. Ion exchange cellulose is the subject of the next article, by C. S. Knight. Introduction of the microgranular type is a distinct advance for protein chromato-Its fundamental properties are discussed and compared with those of the more traditional microfibrillar type. Ion exchange cellulose sheets are also considered, and the article as a whole should provide a better understanding of the performance factors of all three types.

Adsorption gas chromatography, a comparatively neglected field, is covered admirably by A. V. Kisilev who, with others in the Soviet Union, has made important contributions to the subject. The standardized preparation of adsorbents with special properties has considerable potentiality. Applications and potentialities of the packed capillary column are also well brought out in the

main roots of modern clinical medicine. This vital and next article, by I. Halasz and E. Heine. This type of column has a diameter of 0.5 mm or less, and is prepared by drawing out a wider column already loosely filled with granular solid. The packing density of such columns is considerably smaller than that of conventionally packed capillary columns, and consequently they have higher permeability and higher separation power with only a moderate pressure drop. In the next article, by W. M. McFadden, the use of the mass spectrometer in the analysis of gas chromatographic eluants is discussed. The method is extremely sensitive, but interpretation of spectra of unknowns may sometimes be difficult. A good account of instrumentation is given and applications to various types of gas chromatogram are described. The object of the final article, by L. Rohrschneider, is to examine the relationship between polarity of stationary liquid phase as applied to gas chromatography and solvent polarity as deduced from physical chemical properties. possibilities for defining polarity and using this for predicting retention are examined. This is largely a theoretical article which points to important practical implications.

This volume maintains the high standard of the series and contains something of interest for all who use chromatographic methods. R. Consden

MORE HETEROCYCLIC CHEMISTRY

Pyrazoles, Pyrazolines, Pyrazolidines, Indazoles and Condensed Rings

By Lyell Behr, Rafaello Fusco and C. H. Jarboe. Edited by Richard H. Wiley. (The Chemistry of Heterocyclic Compounds: a Series of Monographs.) Pp. xvi+888. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1967.) 450s.

Specialists in the field of heterocyclic chemistry cannot do otherwise than welcome this new volume of collected information on pyrazoles and related types, painstakingly compiled, in very great detail, by the three authors. To quote from the editor's preface, the work covers "the transition from the classical period (1890-1920) through the development of the modern period (1905-1960)" and presents the research worker with necessary information on almost all known pyrazoles and their derivatives named in the title, in the form of preparative methods, properties, both physical and chemical, interspersed with good critical discussion. Physical methods for elucidation of structures are also well recorded. The reader is thereby saved much valuable time which would otherwise be spent in searching the literature on a subject which is very widely dispersed.

The book is in four parts. The first part, on pyrazoles themselves, is by Rafaello Fusco, whose name is well known in this field. The factual information is presented in a readable style with interesting discussion, and the section ends with a list of 1,161 references. The section is supplemented by the fourth part of the book, which comprises 110 tables, classifying pyrazoles into ten groups according to substituents, together with the main synthetic methods, physical characteristics, references, and some of the chief derivatives with their melting-points. One minor criticism could be directed at some of the formulae, which look a little odd, because of the author's determination to show which atom of a substituent is attached to the nucleus. It seems unnecessary to write H₅C₆- or H₅C₂OOC- just because the group is on the left.

The second part of the book, by C. H. Jarboe, covers the chemistry of pyrazolines and pyrazolidines equally exhaustively. The factual data are leavened by a certain amount of lively comment, and one may read "It was finally shown, amid much acrimony, that they were pyrazoline carboxylate esters" (page 195), or again, of a certain 1-pyrazoline, that the half-decomposition period is 34 minutes at 100°, and 9 years at 25° (page 207). An extensive list of references follows.

The third part, by L. C. Behr, dealing with indazoles and condensed systems, is also a good factual summary, providing an insight into the structural problems, and indicating the main lines of research which remain to be followed. References are again very numerous.

Regrettably, with such a wealth of material in one volume, the printing is close, and some of the structural formulae absurdly small. The older generation of chemists would do well to provide themselves with a good handlens!

W. J. BARRY

FIESER'S REAGENTS

Reagents for Organic Synthesis

By Louis F. Fieser and Mary Fieser. Pp. vii+1457. (New York and London: John Wiley and Sons, Inc., 1967.) 210s.

EVER since Louis Fieser's sixty-sixth birthday, two years ago, when his publishers announced the forthcoming publication of this book, we have been waiting eagerly for what promised to be a unique and extraordinarily useful book. The authors set out to list the reagents of organic chemistry, including under this heading catalysts, compounds like N-bromsuccinimide in which only part of the molecule is transferred, and compounds like tetraphenylcyclopentadienone in which the whole molecule can be present in the product. Because, when reagent is thus defined, every reaction of organic chemistry has a claim to inclusion, the book is necessarily selective. It is no surprise that in most cases the Fiesers have made the obvious choices of what to leave out.

The authors very largely achieve what they set out to do. In a check of a few reagents we wanted to use recently, we found all but three adequately covered (no purification for amyl nitrite [perhaps the American product needs no purifying], no entry for potassium or sodium cyanide, no entry for dimethylamine). But no one will find everything he wants in a book of this sort; it is a tribute to its success that we found so much and that our failures were so trivial. Indeed, because it is so inclusive that many people are going to become dependent on it, those relatively unusual reagents which have not been included are even likelier than before to get buried.

This book also has the fascination of a good dictionary: setting out to look up one reagent, one is continually waylaid by other absorbing entries, the more arcane the better. I not only came across all sorts of reactions I did not know about, but was continually entertained as I read, and almost found myself reading from cover to cover, no part of a reviewer's brief, I think, with this kind of book.

My one criticism (apart from the price, for which there are no doubt reasons) is that the organization into reagents occasionally leads to fragmentation of things that might be better treated as one topic. I can illustrate this with the example of enamines which appear under several headings: as a protecting group in a hydride reduction, under dibenzoyl peroxide (not indexed under enamines), under morpholinocyclohexene (not indexed), under ozonolysis, under sodium borohydride, under piperidine (not indexed), under pyrrolidnocyclohexene (not indexed), under 1,3-dichloro-2-butene (not indexed) and under toluene-sulphonic acid. Now the indexing failures are trivial; but in this kind of case an entry under the general heading enamines, rather than under several more specific headings, would do much for an understanding of the usefulness of the class and also afford an opportunity for a brief discussion of, in this example, the relative merits of the pyrrolidine and morpholine enamines. This would, of course, be no small task and I would

certainly hesitate to tackle it myself on the scale of the whole book,

This criticism is by way of saying that the book is so useful that one half expects to find everything in it.

IAN FLEMING

OBITUARIES

Professor Francis Bitter

On November 21, 1967, the National Magnet Laboratory at the Massachusetts Institute of Technology was rededicated as the Francis Bitter National Magnet Laboratory. Professor Bitter, long a leader in research on magnetism at MIT, died on July 26 in Centerville, Massachusetts, after a protracted illness.

Bitter, born in Weehawken, New Jersey, on July 22, 1902, was the son of Karl Bitter, a well known British sculptor. He attended the Taft School, and received the Bachelor of Science degree from Columbia University in 1924. After spending a year in Berlin, where he attended lectures by Einstein, Planck, and von Laue, young Bitter returned to Columbia, receiving the Ph.D. degree in 1928. In his thesis work he used a large electromagnet while studying the diamagnetic susceptibilities of organic gases, and during two years as a National Research Fellow at the California Institute of Technology, he worked further on magnetic problems under the direction of R. A. Millikan. In 1930 he joined the Westinghouse Research Laboratories in Pittsburgh, where he carried out applied research on ferromagnetism.

Bitter spent 1933-34 as a Guggenheim Fellow at the University of Cambridge, where he became interested in Kapitza's work on powerful pulsed magnetic fields. Returning to the United States as an associate professor in the Department of Metallurgy at MIT, he set out to develop magnets which would be capable of producing more intense, constant and uniform fields than had previously been available. He attacked this problem effectively by shifting the large masses of iron previously used in electromagnets from the magnets to the generators from which they obtained power. What came to be known as the Bitter magnet is a solenoid carefully designed to provide rapid heat removal by intimate contact with a large volume of water flowing through its turns. A magnet he designed for Zeeman effect studies in 1938 produced 100,000 Gauss, constant to 1/10 per cent and uniform within the same limits throughout a volume of 10 ml.

After serving for five years as a commander in the Naval Reserve, working on magnetic detection of submarines, counter-measures for magnetic mines and operations research, Bitter returned to MIT as a professor of physics, where he became active in research on nuclear magnetism and the optical effects of microwave resonance. He made important contributions to the theory of optical pumping.

Bitter's temperament was an interesting amalgam of the artistic and the scientific. The breadth of his scientific interests is indicated by the fact that he was successively professor of metallurgy, of physics and of geology and geophysics. Teaching was one of his favourite occupations, and he was an effective adviser to students, serving as master of Ashdown House at MIT from 1960 to 1965. He was active in the planning of courses and curricula, and was the author of several textbooks.

A large number of his colleagues, former students and friends gathered to honour his memory at a symposium on magnetism held in connexion with the re-dedication of the laboratory he helped to found.

GEORGE R. HARRISON

Appointments

MR HUBERT E. SAUTER, at present deputy director, has been appointed director of the US Clearinghouse for Federal Scientific and Technical Information.

Announcements

THE Agricultural Research Council has announced that Ditton Laboratory in Maidstone, Kent, will become a part of East Malling Research Institute, also in Maidstone, in April 1969. The new director who will take over from the two present directors—Dr R. G. Tomkins at Ditton and Dr R. F. Tubbs at East Malling—has not yet been named. The first move in the break-up of the laboratory at Ditton occurred about two years ago when research workers in the biochemistry department moved to the Food Research Institute in Norwich. The remaining staff will be split up between East Malling Institute and the Glasshouse Crops Research Institute in Sussex. Although East Malling and Ditton are essentially independent, some research work, on the conditions for the growth of fruit, has been shared for the past fifteen years.

DR A. G. FRASER, of the Department of Geology, University of Hull, has been awarded a Polar Medal in recognition of his survey work over a period of three years, two of which were spent in the Antarctic.

THE 87th annual general meeting of the Society of Chemical Industry is being held in Edinburgh during July 17-20, 1968. The chief feature of the meeting will be a two-day symposium on "The Future of the Petrochemical Industry". Further information can be obtained from Dr Magnus Pyke, Publicity Secretary, Scottish Grain Distillers, Ltd., Glenochil Research Station, Menstrie, Clackmannanshire, Scotland.

Meetings

Low Temperature Physics, August 21-28, 1968, St. Andrews (The Conference Secretary, School of Physical Sciences, University of St. Andrews, North Haugh, St. Andrews, Scotland).

INDUSTRIAL Measurement Techniques for On-Line Computers, June 10-14, 1968, Institution of Electrical Engineers (Conference Department, IEE, Savoy Place, London WC2).

CODATA Conference on the Critical Evaluation of Numerical Property Values in the Physical Sciences, June 30-July 5, 1968, Arnoldshain, near Frankfurt/Main (Dr Guy Waddington, Executive Director, Central Offices, CODATA, c/o National Academy of Sciences, 2101 Constitution Ave. NW, Washington, DC).

FEDERATION of European Biochemical Societies, July 15-20, 1968, Prague (The Secretariat of the Fifth FEBS Meeting, Nám Krasnoarméjců 1, Prague 1, Czechoslovakia).

PATTERN Recognition, July 29-31, 1968, National Physical Laboratory, Teddington, Middlesex (The Conference Department, The Institution of Electrical Engineers, Savoy Place, London WC2).

ERRATUM. In the second and third sentences of the article "Triads in Foetal Skeletal Muscle" by Sheppard M. Walker and G. Randolph Schrodt (Nature, 216, 985; 1967) "the Z level of the line" should read "the level of the Z line". In the second line of the legend to Fig. 6 "right" should read "left".

In the communication "Imidazole and Sequestration of Calcium Ions by Sarcoplasmic Reticulum" by B. P. Yu, E. J. Masoro and F. D. DeMartinis (Nature, 216, 822; 1967) the figures were wrongly numbered. Fig. 3 should be Fig. 5, Fig. 4 should be Fig. 3 and Fig. 5 should be Fig. 4. Text references to figures are correct for this revised numbering.

CORRESPONDENCE

Food Antioxidants in Tissue Culture

SIR,-Miss Milner has described some very interesting experiments on the effects of butylated hydroxytoluene (BHT) and related compounds on monkey kidney cells in tissue culture1, but it is a pity that she should have balked at the task of interpreting her findings in terms of the safety in use of BHT as a food antioxidant. Having spoken in three successive sentences of p.p.m. in individual items of food for human consumption, mg/kg body weight doses in animal experiments and p.p.m. in tissue culture media, without suggesting how these might be inter-related, she abdicates all responsibility by concluding that "...it is difficult to make a direct comparison with the in vivo experimental results because of the different effects measured".

Of course the selection of parameters to measure is at the discretion of the experimenter, but another source of difficulty in this instance is the absence of any data on the kidney concentrations of BHT in animals receiving BHT in the diet.

Because unchanged BHT is not excreted in the urine of rabbits receiving doses of up to 1 g/kg body wt2 it seems unlikely that the kidney concentrates this compound. We are, however, in the process of investigating this aspect of BHT metabolism.

In the meantime, reported results from liver analyses may be of interest. Daniel and Gage³ found that rats given 5,000 p.p.m. BHT in the diet averaged less than 2 p.p.m. BHT in the liver. Thus the amounts of BHT in the diet required to produce liver concentrations of 7.5-30 p.p.m. (those used by Miss Milner) would exceed the LD₅₀ of this compound in the rat⁴. Legal tolerances would allow an average BHT content of up to 4 p.p.m.5 in the human diet. In fact, the present dietary concentration in Great Britain is unlikely to exceed 1 p.p.m. If the intake and liver content of BHT have the same relationship in man as they do in the rat, the human liver would currently contain about 3×10^{-4} p.p.m.

We hope that these comments may help in the interpretation of the tissue culture data1 and in the design of further experiments to help us bridge the gap between animal studies and the human situation. But progress in this direction will only be possible if the results obtained with tissue cultures are considered against the background of toxicological data already in our possession.

Finally, one detail calls for correction. While it is true as stated that BHT is permitted for use in butter, this permission only applies to butter for manufacturing purposes6,7; this means that the addition of BHT to butter for retail sale in Great Britain is illegal.

Yours faithfully,

D. GILBERT A. D. MARTIN

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Thursday, December 28

ROYAL INSTITUTION (at 21 Albemarle Street, London, W1), at 3 p.m.—Professor Richard L. Gregory "The Intelligent Eye". (The One Hundred and Thirty-Eighth Course of Six Lectures Adapted to a Juvenile Auditory. Further lectures on December 30, January 2, 4, 6 and 9).

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

dates mentioned:
TEMPORARY LECTURER or ASSISTANT LECTURER (preferably qualified to teach philosophy of science) in the DEPARTMENT OF PHILOSOPHY—The Registrar, University College of North Wales, Bangor, North Wales (January 1).
ASSISTANT EXPERIMENTAL OFFICER (with a degree or equivalent in botany, horticulture, agriculture or a related subject) for work on the breeding of vegetable crops, particularly in Brassicae—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (January 5).
LECTURER IN ANATOMY—The Secretary, The University, Dundee, Scotland (January 6).

land (January 6).

RESPARCH FELLOW or ASSISTANT (graduate in mathematics, physics or electrical engineering) in ENGINEERING for studies in the synthesis of lumped linear electrical networks—The Registrar, University of Leicester, Leicester

(January 6).

CHAIR OF EDUCATION—The Registrar, University of Warwick, Coventry, CV4 7AL (January 8).

LECTURER (with previous research experience in the biochemical aspects of drug metabolism and distribution) in BIOPHARMACY—The Secretary, Chelsea College of Science and Technology, Manresa Road, London, SW3

of drug metabolism and distribution) in Biopharmacy—the officerosty Chelsea College of Science and Technology, Manresa Road, London, SW3 (January 8).

Lecturer in Medicine in the University Department of Medicine, Western Infirmary—Secretary to the University Court, The University, Glasgow (January 13).

Lecturer (preferably with interests and substantial experience in low temperature physics, reactor physics or electronics) in the Department of Physics, and a Senior Research Associate in the Department of Physics, and a Senior Research Associate in the Department of Physics, and a Senior Research Associate in the Department of Physics, and a Senior Research Associate in the Computer Centre.—The Assistant Registrar (S), University of Birmingham, Box 363, Birmingham 15 (January 14).

Assistant Lecturers, Lecturers in the Computer Centre—The Registrar, University of Essex, Wivenhoe Park, Colchester, Essex, quoting Ref. MS/12 (January 15).

Lecturer of Assistant Lecturer in Botany—The Registrar, The University, Hull (January 15).

PROFESSOR OF CHEMISTRY at University Council, 33 Bedford Place, London, WC1 (January 16).

Senior Lecturer/Lecturer in the School of Physiology, University of Mew South Walcs—The Association of Commonwealth Universities (Branch Office), Mariborough House, Pall Mall, London, SW1 (Australia and London, January 15).

SENIOR LECTURER/LECTURER in the School of Physiology, University of New South Wales—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, January 15).

CHAR OF BOTANY at Fourah Bay College, University of Sierra Leone—The Inter-University Council, 33 Bedford Place, London, WC1 (January 18).

LECTURERS (2) (preferably with experience in teaching sociological methods and sociology of African societies) in Sociology at the University of East Africa, University College, Dar es Salaam—The Inter-University Council, 33 Bedford Place, London, WC1 (January 18).

SEMIOR LECTURER OF LECTURER IN BIOCHEMISTRY at Victoria University of Wellington, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (New Zealand and London, January 19).

DIRECTOR (with research experience in a field dealing with the production, processing and marketing of meat and meat products) of the M. C. Franklin Laboratory and William McIlraith Fellow in Animal Husbandry at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (London and Australia, January 26).

BAIRD AND TATLOCK RESEARCH FELLOW IN SCHENCE EDUCATION at the University of Zambia—The Inter-University Council, 33 Bedford Place, London, WC1 (January 27).

LECTURER OF SENIOR LECTURER (preferably with research experience in blophysicai, or physico-chemical aspects of respiratory or circulatory physiology) in the Physiological Flow Studies University of Caro, Imperial College of Science and Technology, London, SW7 (January 31).

RESEARCH FELLOW (with a good knowledge of the techniques of protein chemistry, including amino acid analysis, sequence determinations, and the methods for studying active centres of enzymes) in Biochemistry in the John Curtin School of Medical Research, Institute of Advanced Studies, Australia and London, January 31).

CHAIR OF CELL BIOLOGY, HISTOLOGY

SENIOR LECTURER OF LECTURER IN PHYSICS at Victoria University of Wellington, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (New Zealand and London, February 20).

BIOCHEMIST OF MICROBIOLOGIST in the BACTERIOLOGY DEPARTMENT for a group working on the natural defence mechanisms of the adder against infection by mastitis pathogens—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, Berkshire, quoting Ref. 67/25 (3).

JUNIOR TECHNICIAN/TECHNICIAN (male or female, preferably with experience of electron microscopy and histology) for a Research UNIT—The Establishment Officer, University College London, Gower Street, London, WCI, quoting Ref. Anat./11.

POSTDOCTORAL RESEARCH ASSISTANT IN GAS KINETICS for research on kinetics of Levis acid-base reactions in the gas phase—The Registrar, University College of Wales, Aberystwyth.

SENTION TECHNICIAN (preferably with histological training) in the BIOLOGY SECTION of the University Examination Laboratorics, for duties which will include work in connexion with University practical examinations at all levels, and in particular the making of permanent biological microscopical preparations—The Clerk to the Senate, University of London, Senate House (11/N), London, WCI.

TECHNICIAN (female, aged 18–23, preferably with experience of horticulture and laboratory work) in the Department of Horticulture—Professor O. V. S. Heath, FRS, University of Reading, Horticultural Research Laboratories, Shinfield Grange, Shinfield, Reading, Berkshire.

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one or two copies of NATURE each week is:

*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire..... United States of America. (by air freight) \$48 each
Canada (by air freight) \$52 each
Elsewhere overseas by surface mail £14.0.0 each (Charge for delivery by air mail on application)

*Shorter periods pro rata. (Minimum three months.)

MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

12 MONTHS (52 issues and 4 indexes)

Number of Copies	G.B. & Eire	U.S.A. (by air	Canada freight)	Elsewhere (surface mail) Each £13.10.0 £12.15.0 £12.0.0
3–5 6–11 12 or more	Each £13.10.0 £12.15.0 £12.0.0	Each \$46.50 \$44.50 \$42.50	Each \$50.50 \$48.30 \$46.00	

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address. (ZIP essential for U.S.A.)

APPOINTMENTS VACANT

UNIVERSITY OF MALAYA

UNIVERSITY OF MALAYA

FACULTY OF AGRICULTURE

Applications are invited for the post of Lecturer Assistant Lecturer in AGRICULTURAL BIOCHEMISTRY. Applicants should have preferably an Honours degree (or the equivalent) in Science or Agricultural Science and a higher Degree in Biochemistry, or an Honours Degree (or the equivalent) in Biochemistry with a Higher Degree in Agricultural Science, Nutrition or Plant Science, or some similar combination of subjects. Duties consist mainly in teaching the one-year course in Agricultural Biochemistry towards the four-year B.Agr.Sc. Degree and supervision of research projects by graduate students. The one year course serves as a basis for subsequent Plant and Animal Nutrition and Physiology courses. Good laboratory facilities are available for research into biochemical aspects of plant, animal or food sciences.

Salary Scales: (approximate sterling equivalents) Lecturer £1.408 by £65 to £1.890 £61.000

animal or food sciences.

Salary Scales: (approximate sterling equivalents), Lecturer, £1,498 by £65 to £1,889/£1,954 by £73 to £2,320 per annum; Assistant Lecturer, £1,303 by £65 to £1,433 per annum. In addition, the following allowances are payable:

Variable Allowance: 35 per cent of basic salary, subject to certain maxima depending on marital status; minimum £244 per annum, maximum £651 per annum.

Inducement Allowance: (if awarded) process (5)

mum £651 per annum.

Inducement Allowance: (if awarded), varies (a) for Lecturers, up to £488 per annum; (b) for Assistant Lecturers up to £326 per annum.

Housing will be provided, if available, for which a rent of £163 to £204 per annum will be charged.

Provident Fund: Staff member contributes 5 per cent and University 15 per cent of basic sealors.

Further particulars and application forms are obtainable from the Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1. The closing date for the receipt of applications in Kuala Lumpur and London is January 15, 1968.

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING (UNIVERSITY OF READING)

BACTERIOLOGY DEPARTMENT

BACTERIOLOGY DEPARTMENT

Biochemist or microbiologist required for a group working on the natural defence mechanisms of the udder against infection by mastitis pathogens. The natural inhibitors and antibodies in bovine blood, milk and mammary glands are being studied. The successful candidate should be able to register for a Higher Degree, Appointment to grade of Scientific Officer (£926 to £1,574) or Senior Scientific Officer (£926 to £2,155) according to age and experience.

Apply to Secretary, N.I.R.D., Sninfield, Reading, naming two referees and quoting reference 67/25(3).

UNIVERSITY OF LONDON READERSHIP IN SCIENCE OF MATERIALS AT QUEEN MARY COLLEGE

AT QUEEN MARY COLLEGE

The Senate invite applications for the Readership in Science of Materials tenable at Queen Mary College. The requirement is for a physical metallurgist preferably with knowledge in the fields of phase transformations, X-ray analysis and chemical thermodynamics. Experience in industry would be an asset but close contact with modern metallurgical industry is essential. Salary scale £2,575 by £105 to £3,415 plus £80 London Allowance.

Applications (ten copies), must be received not

Allowance.

Applications (ten copies), must be received not later than February 1, 1968, by the Academic Registrar (N), University of London, Senate House, W.C.I., from whom further particulars may be obtained.

CSIRO

AUSTRALIA

PLANT PHYSIOLOGIST

DIVISION OF PLANT INDUSTRY **RIVERINA LABORATORY**

GENERAL. The Riverina Laboratory of the Commonwealth Scientific and Industrial Research Organization, Division of Plant Industry located at Deniliquin, N.S.W., is approximately 180 miles from Melbourne and 300 miles from the Headquarters of the Division of Plant Industry at Canberra. It has a professional staff of thirteen and is well supported by assistant staff, laboratory and field station facilities. Research is concerned with the maintenance and use of the Biological Resources of Arid and semi-Arid lands with special reference to the Riverina plain of South-East Australia.

Deniliquin has a population of 6,500 and is served by air, rail and bus services. Secondary education is available. Suitable housing may also be arranged.

DUTIES. The appointee will be responsible for initiating a research programme into one or more of the following physiological aspects of plant water relations: (1) the ability of semi-arid and arid zone plant species to tolerate desiccation, (2) the fundamental relationships between water stress and growth of these species, (3) mechanisms for restriction of water loss. Such a programme could be associated with the work of other staff who will be studying the behaviour of dryland communities and related soil water problems.

QUALIFICATIONS. Applicants should have a Ph.D. degree or have had relevant postgraduate experience of equivalent standard and duration, supported by satisfactory evidence of research ability.

SALARY. Depending upon qualifications and experience, the appointment will be made within the salary ranges of Research Scientist, \$A5,250-\$A6,622 p.a. or Senior Research Scientist, \$A6,892-\$A7,974 p.a. Salary rates for women are \$A428 p.a. less than the corresponding rates for men. Consideration of appointment at a higher level would be given to applicants with an outstanding record of research achievement. Promotion within CSIRO to a higher classification is determined by merit.

CONDITIONS. The appointment will be for an initial period of three years, after which an extension of tenure or appointment for an indefinite period would be considered. An Indefinite appointment carries with it Commonwealth Superannuation Fund or Provident Account privileges. Fares paid for the appointee and his dependent family. Further particulars supplied on application.

Applications (quoting Appointment No. 132/169), and stating full name, place, date and year of birth, nationality, marital status, present employment, details of qualifications and experience, together with the names of not more than four persons acquainted with the applicant's academic and professional standing, should reach:

Mr. R. F. Turnbull, Chief Scientific Liaison Officer Australian Scientific Liaison Office,

Africa House, Kingsway, London, W.C.2, by the 19th January, 1968.

(2092)

GRADUATE IN AGRICULTURE, SCIENCE, OR VETERINARY MEDICINE

required by

AN FORAS TALUNTAIS (The Agricultural Institute) for a research AN FORAS TALONTAIS (The Agricultural Institute) for a research project involving toxicological and metabolic studies in cattle in its Animal Sciences Division. Salary according to qualifications and experience. Appointment initially for one year. Facilities available, if necessary, for studies towards the attainment of a higher degree. ESSENTIAL: Either (a) An Honours University Degree, or equivalent, in Agricultural Science or Science or (b) A Degree in Veterinary Medicine, or equivalent.

Application forms from the Director, An Foras Taluntais, 33 Merrion Road, Dublin 4. (Tel.: 693222.) Latest date for receipt of completed forms, January 18, 1968.

(2095)

NESTLE SWITZERLAND IS LOOKING FOR A

FOOD MICROBIOLOGY SPECIALIST

for the central laboratories in Vevey, Switzerland.

In view of the extensive scientific and administrative responsibilities to be entrusted to this specialist, we require a person having:

• specialised post-graduate training in microbiology with doctorate if possible a knowledge of French and German

an aptitude for writing scientific reports and papers

The successful candidate, who will work in a department of chemists and microbiologists, will be responsible for developing new bacteriological methods for the quality supervision of food products.

He will also hold the important function of adviser to the regional laboratories and factories, helping them to co-ordinate their activities in the sphere of raw materials and production control.

Candidates are invited to submit detailed applications to:

NESTLÉ. NESTLE, Service du Personnel, (Pers. PA-NI), 1800, Vevey, SWITZERLAND.

(2087)

BEECHAM RESEARCH LABORATORIES **BROCKHAM PARK** BETCHWORTH, SURREY

have the following vacancy in the Immunochemistry Department at their fundamental research establishment for a

RESEARCH IMMUNOLOGIST

to undertake research as a member of a young and enthusiastic team in the field of allergy, with particular reference to IN VIVO aspects of the mechanism of the allergic reaction.

Research experience in immunology is preferred, but not essential, as the person appointed will be encouraged to develop his or her own approach to the problems involved.

A good Honours Degree in a biological science is necessary, and post-graduate experience would be preferred.

Beecham Research Laboratories is part of the Beecham Group and is situated in a pleasant area of Surrey within easy reach of London. There has been steady growth over the past years and this is expected to continue. There are excellent dining facilities and a flourishing sports and social club.

A competitive starting salary is offered, which will be reviewed regularly and we offer generous fringe benefits which include profit sharing and a non-contributory pension scheme.

Please apply, stating briefly age, qualifications and experience, to: The PERSONNEL OFFICER, BEECHAM RESEARCH LABORATORIES, BROCKHAM PARK, BETCHWORTH, SURREY.

CONTROL **ENGINEERING**

Current research problems at Capenhurst—such as electrical machines; arcs and plasmas; distribution systems and equipment; human environment—present a range of control engineering problems and we wish to strengthen the team working in these areas by the appointment of a young ENGINEER (or MATHEMATICIAN) who will work on the design and analysis of control systems.

Ref. N/90.

NEW MATERIALS

We wish to extend the work on novel electrical motors by a thorough investigation of the design of new materials for such machines. These materials will probably have composite properties and an ideal background for this work would combine training and experience in METALLURGY, MATERIALS generally, and SEMI-CONDUCTOR work with particular reference to their mechanical and electrical properties.

Ref. N/91.

For all of the above posts inlitial salary, depending on ability, experience and age,

ror all of the above posts initial salary, depending on ability, experience and age, will be within one of the following salary bands: £980-£1.675; £1.605-£2.045; £1.825-£2.470; £2.430-£3.025.

Please apply, or write for further interests.

£2,470; £2,430-£3,025.
Please apply, or write for further information. to:
D. C. Pare. Head of Personnel Services,
THE ELECTRICITY COUNCIL RESEARCH CENTRE,
Capenhurth, near Chester,
quoting appropriate reference. (1047)

UNIVERSITY OF HONG KONG SENIOR LECTURESHIP/LECTURESHIP/ ASSISTANT LECTURESHIP IN APPLIED MATHEMATICS

MATHEMATICS

LECTURESHIP/ASSISTANT LECTURESHIP
IN PURE MATHEMATICS

Applications are invited for a post of Senior
Lecturer, Lecturer or Assistant Lecturer in Applied Mathematics, and a post of Lecturer or
Assistant Lecturer in Pure Mathematics. Candidates for the post in Applied Mathematics. Candidates for the post in Applied Mathematics shou'd
specialize in mathematical methods or theoretical
physics, and candidates for the post in Pure
Mathematics should preferably specialize in functional analysis, geometry or topology.

Annual salaries (superannuable) are: Senior

tional analysis, geometry or topology.

Annual salaries (superannuable) are: Senior Lecturer: \$HK47.360 by \$HK1.840 to \$HK56.560; Lecturer. \$HK30.880 by \$HK1.440 to \$HK49.600 (man) or \$HK26.720 by \$HK1,760 to \$HK32.000 to \$HK33.280 by \$HK2,000 to \$HK45.280 by \$HK1,440 to \$HK45.280 by \$HK1,440 to \$HK49.600 (woman); Assistant Lecturer: \$HK20.800 by \$HK1,440 to \$HK25.120 (man) or \$HK15.760 by \$HK1,520 to \$HK20,320 (woman), (\$HK14.60=£1.)

Appropriate increments may be allowed for approved experience after the age of 27, for appointment at Lecturer level.

Senior Lectureships and Lectureships are permanent appointments. Assistant Lectureships are for three years only, but Assistant Lecturers, it considered suitable, are promoted to Lecturer by the end of that period.

The equivalent of income tax in the Colony is comparatively low (at present from about \$HK656 to \$HK3,248 per annum for a married man with two children on a Lecturer's salary). There is a contributory Superannuation Scheme (5 per cent employee, 12½ per cent employer).

An appointee whose place of permanent home is agreed to be overseas is provided with accommodation at reasonable rental and economy-class air passages (or sea passage of the equivalent cost) on first appointment and on leaves. An appointee at Senior Lecturer level whose place of permanent home is not overseas is also provided with accommodation at reasonable rental.

Further information and application forms may be obtained from the Association of Commonwealth Universities (Branch Office), Marlborough House; Pall Mall, London, S.W.1. Applications close in Hong Kong and London on January 22, 1968.

ZOOLOGY LABORATORY TECHNICIAN (male), Queen Mary College (University of London), Mile End Road, E.1. Previous experience in a physiological laboratory is essential. Salary according to experience and qualifications. Scale £653 to £938 per annum plus London Weightling £60 per annum and possible £30 or £80 special qualification award. Five-day week. Four/five weeks annual leave. Pension scheme.—Letters only to Registrar (ZT), stating full details of age, experience and present work. (2081)

UNIVERSITY OF THE WITWATERSRAND **JOHANNESBURG**

DEPARTMENT OF BOTANY

SENIOR LECTURER OR LECTURER IN PLANT PHYSIOLOGY

Applications are invited for appointment to a post of Senior Lecturer or Lecturer in Plant Physiology in the Department of Botany. The salary scales payable are: Senior Lecturer, R.4,200 by R.150 to R.4,800 by R.300 to R.5,700; Lecturer, R.3,150 by R.150 to R.4,800 (at the new rate of exchange R.1,716=£1 stg.) In addition an annual vacation savings bonus of up to R.200 is payable. Membership of the Associated Institutions Pension Fund is compulsory. Membership of the Staff Medical Aid Fund is also compulsory for an officer who is eligible for membership.

Intending applicants are advised to obtain a copy of the information sheet relating to the above vacancy from the Association of Commonwealth Universities (Branch Office), Marlbordugh House, Pall Mall, London, S.W.1. Applications close in South Africa and London on January 15, 1968. Duties are to be assumed on April 1, 1968, or as soon as possible thereafter.

THE DEPARTMENT OF PHYSIOLOGY and Pharmacology, Ontario Veterinary College, University of Guelph, Guelph, Ontario, Canada, requires four faculty members to meet growing teaching and research needs, Persons interested in the following positions are invited to send curriculum vitae, grade transcripts, list of publications, and special qualifications and interests to Dr. H. G. Downie, Professor and Head of the Department.

- to Dr. H. G. Downie, Professor and Head of the Department.

 1. D.V.M. (or equivalent) with Ph.D. in Pharmacology. Duties include participation in the team approach to teaching undergraduate and graduate Pharmacology, and research in areas of own interest. Rank; Associate Professor.

 2. D.V.M. (or equivalent) with Ph.D. in Pharmacology, Toxicology, or Biochemistry. Duties include participation in the team approach by teaching undergraduate and graduate Toxicology and Pharmacology, administrative supervision of a veterinary toxicology testing laboratory, and research and development in forensic analysis. Rank: Associate Professor.

 3. D.V.M. (or equivalent) with Master's degree in any related science. Duties include participation in the team approach to teaching undergraduate Pharmacology. The candidate would be expected to pursue graduate work at the Ph.D. level in Pharmacology. Rank: Lecturer.

 4. PHYSIOLOGIST with Ph.D. qualification. Duties include instruction in Physiology to Physical Education undergraduates and participation in a laboratory course on Human Physiology. Consideration will be given to those individuals having a special research interest in respiratory or cardiovascular physiology. Rank: Assistant Professor.

 Moving expenses up to \$1,000 will be provided for each position. All salaries are commetitive

Moving expenses up to \$1,000 will be provided in each position. All salaries are competitive ith industry. (2074) with industry.

UNIVERSITY COLLEGE OF **NORTH WALES**

THE MARINE SCIENCE LABORATORIES MENAI BRIDGE

Applications are invited for a Post Doctoral Fellowship or Post Graduate Assistantship to study the mechanism of cold hardiness in marine invertebrates. The post will be a full-time appointment, initially for a period of three years.

The salary in the case of a Post Doctoral Fellow would be in the range, £1,105 to £1,340 plus F.S.S.U. benefits or for a Post Graduate Assistant, £760 to £865 plus F.S.S.U. benefits, If a Post Graduate Assistant is appointed, he will be allowed to read for a higher degree, subject to the terms and conditions of an S.R.C. studentship.

ship.
Applicants should have a first class or upper second class Honours degree or have had research experience in the field of electronmicroscopy or biochemistry.
Applications, giving details of age, qualifications and experience, together with the names and addresses of two referees, should be sent before January 8, 1968, to the Registrar, from whom further particulars about the post may be obtained. (2085)

PHARMACOLOGIST

Expanding Pharmaceutical Research Laboratory located near Montreal, Canada, is seeking a Ph.D. with 0 to 5 years experience and a good general background in pharmacology.

Opportunity for basic research.

Cambridge, quoting reference number(s) of

LAURENTIAN UNIVERSITY SUDBURY, ONTARIO, CANADA

DEPARTMENT OF GEOLOGY AND GEOGRAPHY

Applications are invited for a new staff position in Mineralogy, appointment effective from September 1, 1968. Duties will include teaching mineralogy and X ray crystallography, some assistance in the development of the first year laboratory, and responsibility for initiating and conducting research in mineralogy and allied fields. Interests and experience in X-Ray analytical procedures are desirable. New Philips X-ray diffraction and spectrographic research equipment are available in the Department. Unique geological setting of Sudbury provides excellent research opportunities, Department to move in the Spring of 1969 to new building presently under construction.

Applicants must have Ph.D. degree, and experience with research programmes as well as teaching ability at the undergraduate level. Salary and rank dependent on qualifications and experience. Please submit complete personal research interests and experience, and the names of at least three referees who are in a position to assess the applicant's character, scholarly ability and aptitude for teaching to: D. H. Williamson, Professor of Geology, Geology Department, Laurentian University, Sudbury, Ontario, Canada. (2052) Applications are invited for a new staff position

GENERAL HOSPITAL SOUTHEND-ON-SEA

SOUTHEND-ON-SEA

Medical Physics Technician (male or female), grade V or IV, according to experience, required in the Physics Department of the above hospital, the duties including work in the radio-active isotope unit. Applicants must have passed the Ordinary National Certificate in Applied Physics or its equivalent. Salary scale for grade V, £711 to £1,004 per annum, or grade IV. £850 to £1,050 per annum. Possibility of residential accommodation for single woman. If required. Further details may be obtained from the Principal Physicist at the Hospital.

Applications, stating age, qualifications and previous experience, together with the names of two referees, to be sent to the Secretary, General Hospital, Southend-on-Sea, Essex, as soon as possible.

UNIVERSITY OF LEEDS DEPARTMENT OF GENETICS

The Department requires an assistant to help with a project involving amino acid sequence determination in a protein. The successful applicant could either be a young graduate in Chemistry or Biochemistry. graduate in Chemistry or Biochemistry, who would have the opportunity for some independent work towards a higher degree, or a technician with appropriate experience. In the former case the appointment would be made as a Research Assistant within the salary range £785 to £975 per annum, in the latter on the Technician scale £683 to £968, with the possibility of promotion to the Senior Technician grade. The appointment will be for three years in the first instance.

Applications, stating age, qualifications

Applications, stating age, qualifications and experience and naming two referees, should be sent to Professor J. R. S. Fincham, the University, Leeds, 2 before January 5, 1968. (2066)

THE CITY UNIVERSITY

The DEPARTMENT OF CHEMISTRY has a vacancy for a

TECHNICIAN

to assist a forward-looking, S.R.C.-sponsored research in which a combination of advanced techniques is used to study reactions on single crystals. The work is varied and experience with high vacuum equipment, the preparation and polishing of metal specimens, or electronics would be useful.

Salary in the range £800 to £850 per

Write to Professor R. C. Pitkethly, The City University, St. John Street, London, E.C.1. (2064)

UNIVERSITY OF WARWICK SCHOOL OF PHYSICS

SCHOOL OF PHYSICS

Applications are invited for LECTURESHIPS in both THEORETICAL AND EXPERIMENTAL PHYSICS available from October 1, 1968. The School of Physics has special interests in solid state physics and the physics of materials, and preference will be given to candidates with experience in this field of research. Salary in the scale £1.470 to £2.630, together with F.S.S.U. benefits. Removal allowance payable.

Further particulars and application forms may be obtained from the Registrar, University of Warwick, Coventry, CV4 7AL; closing date January 15, 1968. (2084)

UNIVERSITY OF WARWICK SCHOOL OF MOLECULAR SCIENCES POST IN BIOCHEMISTRY

POST IN BIOCHEMISTRY

Applications are invited from Biochemists for a Lectureship or Assistant Lectureship in the School of Molecular Sciences. The successful applicant will be expected to assist both in the teaching of undergraduates and in the running of an M.Sc. course in Molecular Enzymology. Salary in the scale of £1.470 by £90 to £2.010 by £85 to £2.180 by £90 to £2.270 (bar) by £90 to £2.630 (Lecturer), or £1.105 by £75 to £1.180 by £80 to £1.340 (Assistant Lecturer), together with F.S.S.U. benefits. Removal allowance payable.

Application forms and further details may be obtained from the Registrar, University of Warwick, Coventry CV4 7AL. Applications should, if possible, be received by January 15, 1968. (2083)

PLANT BREEDER FOR STUDIES IN VEGE-table breeding and their application to develop-ment of improved varieties. A good honours degree in plant science and postgraduate experi-ence in plant breeding or genetics expected. Ap-pointment in grade Scientific Officer (£926 to £1,574) or Senior Scientific Officer (£926 to £2,155), depending on age, qualifications and ex-perience. F.S.S.U.—Applications, quoting three referees, to Secretary, National Vegetable Re-search Station, Wellesbourne, Warwick (from whom further particulars may be obtained), by January 12, 1968. (2082)

UNIVERSITY OF SHEFFIELD CHAIR OF GEOGRAPHY

CHAIR OF GEOGRAPHY

Applications are invited for a CHAIR of GEOGRAPHY which will become vacant on the retirement of Professor Alice Garnett in September, 1968. Candidates should have a special interest and experience within the general field of human geography and, preferably, some research experience in the application of quantitative methods in their chosen field. Salary in the range approved for professorial appointments. F.S.S.U. provision.

Further particulars from the Registrar, to whom applications (fourteen copies), should be sent by February 19, 1968. (2078)

UNIVERSITY OF BIRMINGHAM CHAIR OF CANCER STUDIES

CHAIR OF CANCER STUDIES

Applications are invited for the newly-established Chair of Cancer Studies and the Directorship of the Laboratories of the Birmingham Branch of the British Empire Cancer Campaign. The joint appointment will be held in association with the Division of Pathological Studies in the Faculty of Medicine and Dentistry. Applicants should preferably but not necessarily, have interests in the field of cell biology and/or immunology. Salary in the range: £3,570 to £4,990 (Non-medical and Pre-clinical) or £3,465 to £4,885 (Clinical). F.S.S.U.

Further particulars may be obtained from the Registrar (R.S.). University of Birmingham. P.O. Box 363, Birmingham 15, to whom applications (twelve copies), naming three referees, should be sent by February 12, 1968. (2076)

UNIVERSITY OF VICTORIA VICTORIA, B.C.

DEPARTMENT OF PHYSICS

Applications are invited for faculty positions from July 1, 1968. A Ph.D. is required. Duties will include teaching and research. Preference will be given to applicants with research interests in one of the following fields: Astronomy, Geophysics. Fluid Mechanics, Nuclear Physics. Appointment may be made at any rank depending upon background and experience. Salary floors in 1967-68 are \$14,500 for Professor. \$11,500 for Associate Professor, and \$9,200 for Assistant Professor. Professor.

Letters of application should be sent to Pro-fessor J. L. Climenhaga, Head, Department of Physics, and should include a complete curricu-lum vitae and the names of three or four feet (2075)

QUEEN'S UNIVERSITY KINGSTON, ONTARIO, CANADA DEPARTMENT OF CHEMISTRY

Applications are invited for admission to the graduate programme leading to the M.Sc. and Ph.D. degrees in Theoretical, Physical, Inorganic and Organic Chemistry. Teaching assistantships of \$3,700 involving a maximum of three periods per week laboratory supervision are available. Applications should be made to: Head, Department of Chemistry, Queen's University, Kingston, Ontario, Canada. (2073)

CHRIST'S COLLEGE CAMBRIDGE

CAMBRIDGE

The Master and Fellows of Christ's College propose to elect two schoolmasters as Fellow-Commoners of the College, one for the Michaelmas Term 1968 and another for the Lent Term 1969, in order to provide them with an opportunity to pursue their own intellectual interests and to follow recent developments in their subjects. A schoolmaster Fellow-Commoner will have no duties but he will be expected to reside in Cambridge for the period of Full Term; he will be provided with accommodation, free meals including dinner at High Table, and an emolument of £50. Preference will be given to candidates who have taught for at least seven years, who are below the age of 45, who are not graduates of Oxford or Cambridge, and who are teaching in a direct grant school or a maintained grammar school. It is hoped on this occasion to appoint at least one schoolmaster who teaches a subject or subjects in Natural Sciences.

Applications should be made before March 1, 1968, on the standard application form which should be obtained from, and returned to, the Master, Christ's College, Cambridge, (2070)

PRE- AND POST-DOCTORAL RESEARCH APPOINTMENTS. Biochemistry and Biophysics, competitive stipends, wide selection of research areas.—Inquire to Department of Biochemistry, Oklahoma State University, Stillwater, Oklahoma, 74074. (X1728)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BACTERIOLOGY

Applications are invited from medical candidates for a post of Lecturer in the Department of Bacteriology. The salary will be within the range £1,470 to £3,110 per annum, according to qualifications and experience.

experience.

Applications, stating age, qualifications and experience, together with the names of three referees, should be sent not later than January 17, 1968, to the Registrar, the University, Liverpool 3, from whom further particulars may be obtained.

Please quote Ref.: RV/292/N. (2056)

PROJECT ENGINEERS-MEDICAL ENGINEERING

MEDICAL ENGINEERING

Applications are invited from graduates in aplied or pure science for posts in the medical engineering team of Vickers Limited Research Establishment. The appointees will be required to assist in the development of equipment for both laboratory and clinical use. A main line of work at present in tissue and organ storage for spare part surgery.

The basic qualifications necessary are a good degree, inventive ability and experience in project engineering. Experience in bioengineering could be an advantage.

Applications, accompanied by a brief curriculum vitae, should be addressed to the Controller of Research, Vickers Limited, Vickers Research Establishment, Sunning-hill, Ascot, Berkshire. (2072)

UNIVERSITY OF DUNDEE DEPARTMENT OF PHYSICS

DEPARTMENT OF PHYSICS

Applications are invited from honours graduates for a post of Research Assistant in the Department of Physics to work on X-ray diffraction investigations of virus structure. The post will be supported by a Medical Research Council grant for three years at a salary of £700 per annum. The Research Assistant will be encouraged to read for a higher degree.

Applications, with the names of two referees, should be submitted not later than January 13, 1968, to Professor K. J. Standley, Department of Physics, The University, Dundee, from whom further information may be obtained. (2090)

LIBRARIAN/SECRETARY CANADIAN RED CROSS MEMORIAL HOSPITAL

TAPLOW, NR. MAIDENHEAD, BERKS

Required to take full charge of medical library and assist in preparation of manuscripts, etc. at M.R.C. Rheumatism Research Unit. Post vacant January 1. Salary in accordance with age and qualifications.

Applications to Hon. Director.

(2091)

UNIVERSITY OF LIVERPOOL DERBY CHAIR OF ZOOLOGY

Applications are invited for the Derby Chair of Zoology. The salary will be within the range approved for full-time professorial appointments.

Applications (twelve copies), together with the names of three referees, should be received not later than January 31, 1968, by the undersigned, from whom further particulars may be obtained. (Candidates overseas may send one copy only, by airmail.) Please quote Ref.: RV/295/N.

H. BIRCHNALL.

H. H. BURCHNALL, Registrar.

(2071)

ICI POSTDOCTORAL RESEARCH FELLOWSHIPS

Applications are invited for ICI Research Fellowships tenable under a new scheme commencing October 1st, 1968. Fellowships may be held at the following universities:

University of Aberdeen
University of Aston in Birmingham
Bath University of Technology
The Queen's University of Belfast
University of Birmingham
University of Bradford
University of Bristol
Brunel University
University of Cambridge
The City University
University of Dublin, Trinity College
University of Duhdee
University of Durham
University of East Anglia
University of Edinburgh
University of Essex
University of Exeter
University of Glasgow
Heriot-Watt University
University of Hull
The National University of Ireland
University of Keele
University of Kent at Canterbury

University of Lancaster

University of Leeds
University of Leicester
University of Liverpool
University of London
Loughborough University of Technology
University of Manchester
(including University of Manchester Institute
of Science and Technology)
University of Newcastle upon Tyne
University of Nottingham
University of Oxford
University of Reading
University of St. Andrews
University of Salford
University of Sheffield
University of Southampton
University of Stratholyde
University of Surrey
University of Sussex
University of Wales
(including University of Wales Institute
of Science and Technology Designate)
University of Warwick
University of York

The Fellowships, normally tenable for two years, may be held in any field that falls within ICI's general sphere of interest: this includes many branches of chemistry, physics, the biological sciences, applied mathematics, engineering, and technology. Candidates should not be more than 28 years of age at the date proposed for taking up their Fellowship and must hold the Ph.D. degree or have equivalent research experience.

The initial stipend will depend upon qualifications and experience but will generally be within the range £1,155-£1,365 per annum, together with FSSU benefits. Awards of up to £1,680 may be made to engineers and technologists where industrial experience or other special circumstances warrant it. Up to one year of the tenure of an award may be spent at an approved European research centre. In such cases a small grant may be made towards travel expenses.

Application should be made, not later than February 16th, 1968, to the Registrar/Secretary of the university at which the candidate wishes to pursue his research. Candidates may apply to not more than three universities. In the case of such multiple applications each university must be informed of the other applications and the candidate must clearly state his own order of choice. Strong preference will be given to candidates proposing to carry out their research at institutions other than that from which they make application. Each application must be accompanied by a brief curriculum vitae, a clear indication of the field of research proposed, and the names of two referees. The final choice of candidates will be made by a National Selection Committee, comprising representatives of the universities and of ICI.

HUNTINGDON RESEARCH CENTRE RESEARCH OFFICER

is required to organise a large research project associated with comparative anatomical studies of the respiratory tract. The person appointed will be required to work mainly unsupervised and will be encouraged to publish results. The post carries an attractive salary.

Applications should be made to the Personnel Officer, Huntingdon Research Centre, Huntingdon (Tel. 2522), quoting LEM-T/10/G. (2100)

UNIVERSITY OF CALGARY

DEPARTMENT OF BIOLOGY

invites applications for positions at the level of Assistant or Associate Professor for posts in Invertebrate Physiology, Immuno-logy (or Immuno-temistry), Bacterial Physiology, Environmental Vertebrate Physiology, Developmental Plant Physiology, Anticipated minimum salaries: \$9,500 (Assistant level) and \$13,000 (Associate level).

Applications with curriculum vitae, including names and addresses of three referees, should be sent to:

Dr. J. B. Cragg, Dept. of Biology, The University of Calgary, Calgary, Alberta, Canada. (2099)

WEST OF SCOTLAND AGRICULTURAL COLLEGE ASSISTANT IN CROP HUSBANDRY

ASSISTANT IN CROP HUSBANDRY
Applications are invited for a post of Assistant in the Crop Husbandry Department (headquarters at Auchineruive) from candidates with an appropriate degree (preferably honours) and particular interest in practical and theoretical aspects of experimental work in Crop Husbandry.

The salary, according to age, experience and qualifications, will be on one or other of the following grades: Grade III, £1,396 rising to £2,193; Grade IV, £899 (Honours £926) rising to £1,277.

Conditions of appointment and application forms, obtainable from the Secretary, 6 Blythswood Square, Glasgow, C.2, should be lodged not later than January 12, 1968. (296)

UNIVERSITY OF ABERDEEN CHAIR OF PHARMACOLOGY

Applications are invited for a newly instituted CHAIR OF PHARMACOLOGY, with the Department of Therapeutics and Pharmacology. Further particulars should be obtained from the Secretary, the University, Aberdeen, with whom applications (12 copies) should be lodged by January 20, 1968. (X1898)

RESEARCH ASSISTANT REQUIRED FOR RESEARCH ASSISTANT REQUIRED FOR X-ray crystallography group working on the structure of organic compounds. Candidates should have a degree or comparable qualification in physical sciences or engineering and relevant experience would be useful but not essential. Salary in the range £900 to £1,400.—Apply in writing to: The Superintendent, University Chemical Laboratory, Cambridge. (2077)

HOSPITAL BIOCHEMIST (BASIC GRADE) required. Opportunities for research.—Apply to Dr. D. M. Matthews, Department of Chemical Pathology, Vincent Square Laboratories, 124 Vauxhall Bridge Road, London, S.W.1.

TECHNICIANS SENIOR AND JUNIOR with experience in Pharmacology, required for modern Research Laboratories.—Apply, in writing, with fullest particulars of education, previous experience, etc., to The Research Director. Biorex Laboratories Limited, Apsley House, 198 City Road, London, E.C.1. (2097)

FOR SALE AND WANTED

SCIENTIFIC ALMOST ANY learned periodicals, proceedings, transactions, etc., wanted. Also most books in print supplied.—H. Pordes, 529B Finchley Road, London, N.W.3., Tel.: 01-435 9878. (2065) WM. DAWSON & SONS LTD.

FELLOWSHIPS AND **STUDENTSHIPS**

CHRIST'S COLLEGE CAMBRIDGE

CENTRAL ELECTRICITY GENERATING BOARD FELLOWSHIP

BOARD FELLOWSHIP

The College, in consultation with the C.E.G.B. and the University Department of Metallurgy offers a Senior Fellowship in Metallurgy offers a Senior Fellowship in Metallurgy for a period of five years in the first instance at a stipend of £1,400 per annum by £50 to £1,600 maximum and usual Fellowship privileges and allowances. The Fellow appointed will be required to become a member of the F.S.S.U.

The Fellow will be expected to work in one of the following areas of Materials Science: ceramics, intermetallic compounds, materials for electrical and magnetic applications.

Candidates should send their names, together with a brief curriculum vitae and the subject of their research to the Master before February 1, 1968. It is hoped to proceed to an election in the Lent Term and the date of commencement will then be fixed by arrangement with the successful candidate. (2069)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND

DEPARTMENT OF CHEMISTRY

Several graduate studentships in chemistry are available, value \$2,500 to \$3,100.

Interested applicants who have, or expect to receive, an honours degree in chemistry or graduateship of the R.I.C., or equivalent qualification, should write to: The Head, Department of Chemistry, Memorial University of Newfoundland, St. John's, Newfoundland, Canada, (1841)

Date-1968

11. March 26.

12. April 2.

CHRIST'S COLLEGE CAMBRIDGE

RESEARCH FELLOWSHIP IN PLANT BIOCHEMISTRY

The College proposes to proceed, in consultation with the University Department of Biochemistry and Botany, in the Lent Term 1968, to the election of a Fellow for research in Plant Biochemistry if a candidate of sufficient merit presents himself.

Applicants for this Fellowship should, by the beginning of the Lent Term 1968, have completed three but not more than ten terms of research; but candidates falling outside these limits of standing may be admitted at the discretion of the Master.

The tenure of the Fellowship is for four years with a stipend of £750 a year if the successful candidate is the holder of a Ph.D. degree or £600 if he does not hold such a degree, together with a marriage allowance of £250 a year and a children's allowance of £50 per child a year in appropriate cases. In addition a Research Fellow is entitled to receive rent-free accommodation in College, dinners, and a commons allow-

Candidates should send their names, together with a brief curriculum vitae and the subject of their research, and the names and addresses of two referces, to the Master, before February 1, (2086)

LECTURES AND COURSES

UNIVERSITY OF LEEDS

ELECTRONIC COMPUTING LABORATORY

The Laboratory offers a ONE-YEAR POST-GRADUATE COURSE in ELECTRONIC COMPUTATION leading to the degree of M.Sc.

Please write for further particulars to Professor G. B. Cook, Computing Labora-tory, The University, Leeds, 2. (2067)

WALTHAM FOREST TECHNICAL COLLEGE AND SCHOOL OF ART Forest Road, London, E.17

SCHOOL OF BIOCHEMISTRY AND MOLECULAR BIOLOGY

RADIOACTIVE TRACER TECHNIQUES

Tuesday evenings-6.30-9.30 p.m. JANUARY-APRIL, 1968

This course is designed to give an introduction to the major uses of radioisotopes in inorganic chemistry, organic chemistry, biochemistry and clinical chemistry. The emphasis will be on practical techniques sultable for adaptation to a wide variety of purposes. The course is recognized by the Department of Education and Science as supplying the additional requirements for school teachers as laid down in Administrative Memorandum 1/65.

Introduction. Fundamentals of Radioactivity Physics. Properties of Ionising Radiations. Ionisation Chambers, Proportional counters, Geiger-Müller counters, Scintillation counters. 1. January 16. Properties of Radio-isotopes. Properties of Iionising Radiations. Characteristics of Geiger-Müller counters. Characteristics of Scintillation January 23.
 January 30. 4. February 6. counters.
Double Radioactive Tracer tech-5. February 13. Statistics of Radioactive Assay. niques.
Protection against Ionising Radia-6. February 20. Safe handling of Radioactive Iso-Radioactive Assay. 7. February 27. Principles of Radioactive Tracer Trechniques.
Isotope Dilution Analysis.
Autoradiography.
Neutron Activation Analysis. 8. March 5. 9. March 12. 10. March 19.

Neutron Activation Analytical Tech-General review and discussion.

PRACTICAL WORK

FEE: £4

Application should be made not later than January 9, 1968.

(2093)

The new Elliott 315/X series of watercooled, oil-insulated X-ray spectrographic tubes is suitable for fluorescence analysis and similar work, operating with maximum voltages of 100kV. The spectrally pure radiation output is absolutely constant when fed from a stabilised high voltage generator. This tube will give maximum target ratings of 2kW for tungsten, molybdenum and gold. The built-in 2 mm lead equivalent shielding and pure beryllium window are features of the Elliott X-ray spectrographic tubes.

THE MCILWAIN TISSUE CHOPPER

The original model introduced in 1953 is now fitted with the latest modifications which makes the instrument even more versatile.

Stepless adjustment of slice thickness by means of a micrometer head graduated from 1 to 1,000 microns.

Greater rigidity enables even finer slices to be chopped and up to a maximum of 1 mm thick.

Quick return mechanism to cutting table. Improved method of holding tissue.

Electronic speed control with limit switch.

Extended model available for chopping polyacrylamide gel cylinders.

Please ask for leaflet.

High Accuracy Abbe 60

The normal Abbe Refractometer which reads by estimation to 0.0002, has this limit set by its non-linear scale and the use of compensating prisms to enable measurements to be made with white light. To overcome these restrictions the High Accuracy Abbe 60 has a linear scale capable of accurate sub-division and uses spectral sources thus eliminating the need for compensation prisms. Of course there are snags! Conversion tables have to be used to arrive at the refractive index, but these are made as simple as possible and have the additional advantage that they can be supplied for a wide variety of wavelengths. The important feature is that measurements may be made to an accuracy of 0.00004 over the range of 1.30–1.74.

Abbe 60 Refractometer

We now have capacity for aluminising certain types of mirrors, at short notice.

NATURE Volume 216 DECEMBER 30, 1967

Does every Apple have a Worm?

THE Reith Lectures are a splendid device by means of which the British Broadcasting Corporation provides each year a public platform from which some individual can launch a strictly personal view of the condition of society. Although the lecturers are usually distinguished scholars-often scientists-they and their listeners are usually aware that the best performances are almost by definition the most provocative. Reith lecturer can be counted to have done his job if his listeners are robbed of some natural complacency. It follows that Reith lecturers have a good deal in common with old-fashioned preachers, which implies that people are prepared to tolerate from them a degree of directness and even of piety that would not usually be seemly. There is very little doubt that this year's lecturer, Dr Edmund Leach, the social anthropologist, now also Provost of King's College, Cambridge, has succeeded admirably in conveying to what seems to have been an attentive audience a clear and even controversial view of the problems of modern society. In the process, he has been amusing enough for his assertiveness not to seem too smug, which is more than a little to be thankful for.

Much of what Dr Leach has had to say is concerned with the social consequences of science and technology. Briefly, his theme is that science and technology have now enabled people to change the natural world, not just to understand it. But people—this is the lamenthave not risen to the occasion. As Dr Leach would put it, circumstances require that people should behave like gods, and they persist in behaving like people. One of Dr Leach's examples is the problem of population growth. It is plain, he says, that the trend of population has been "up and up" and that "if the human population goes on increasing continuously at anything like its present rate, then social life as we now know it will rapidly cease to be possible". It does not follow, of course, that a more crowded world would seem intolerable to those who lived in it, for people are remarkably adaptable. But a more crowded world would certainly be different. So does it not follow that people should seek somehow to influence the course of events, first of all perhaps by trying to work out criteria for deciding what kinds of social attributes must be counted desirable? And even if it should prove hard to influence events, is it not more fun-Dr Leach's word—to try to do so and fail than to stand passively aloof from all problems except those which are known in advance to be soluble?

So far, so good. Few would dissent from this opinion. Indeed, it has something in common with the old Edwardian view that the opportunities afforded by

science and technology will enable people to establish a far greater degree of control over circumstances than could have been possible only a few centuries ago. A part of the trouble with Dr Leach's argument is, indeed, that it pays too little attention to the reasons why this cheerfully optimistic view has been modified by the sometimes painful experiences of the past few decades. In the first of his six lectures, he spent a good deal of energy complaining about the "cult of objectivity" among scientists which, the argument goes, is assumed to be a good excuse for not seeking to anticipate the consequences of innovation.

Why do so many of us talk as if the advancing sweep of technology were a natural catastrophe beyond all human control? If you ask a professional scientist that question, he will probably simply reinforce your alarm by insisting that genuine human control is impossible. . . . That being so, the wise man must avoid all involvement in practical affairs; only by detachment can he hope to gair true understanding. That last sentence is a Buddhist precept, but it summarizes the basic philosophy of our science-laden society: all true science must aim at objective truth, and that means that the human observer must never allow himself to get emotionally mixed up with this subject matter. His concern is to understand the universe, not to improve it. Detachment is obligatory. It would be wrong as well as foolish for any scientist to accept responsibility for the practical consequences of his investigations. It is not the scientists' fault that we are threatened by the bomb.

To be fair, Dr Leach went on to admit that this argument may not "seem quite right" even to scientists. The difficulty is that this argument is not simply an exaggeration but a travesty.

The truth is not so much the opposite as something quite different. One of the most important of the developments in science in the past decades has been the spread of the positivist doctrine that objective truth is often an illusion. Particularly in the physical sciences, people are well aware that theories can be no better than the experiments which they suggest. The notion that radically different descriptions of the same system can be equally valid has been commonplace at least since the mid-twenties. This, of course, is why it is unfair of Dr Leach, later in his series of lectures, to tease the high-energy physicists for their attempts to define the properties of particles of matter too unstable to be observed directly. "So what?" is the answer. Logically, these particles are not so much physical realities as testable hypotheses, and the people most of all concerned would probably be as delighted as Dr Leach—though for a different reason—if the concepts were shown by experiment to be invalid. And certainly there is nothing in high-energy physics to justify Dr

Leach's fear that too great a preoccupation with the bits and pieces of which physical systems are made will preclude attempts to deal with systems as a whole.

Much more important, however, is the recognition which has grown up in recent decades of the limitations of the speed with which technical innovations can influence the conditions of society. This is at once a frustration and a safeguard. People still die of tuberculosis, for example. Agricultural productivity is lower than it could be, particularly where the pressure of the population is greatest. Lack of capital, not lack of technical knowledge, restricts the use at present made in developing countries of irrigation schemes, nuclear power stations and even schools and hospitals. Everybody knows that telecommunications are a boon, yet they are grossly under-used in most parts of the world, usually for reasons which have nothing to do with science and technology.

To many scientists, the apparent inertia of society in the face of technical innovation has been a chastening discovery, but it has usually been followed quickly by an avowal that the social sciences contain the means by which science and technology can be more tightly geared to the needs of society as a whole. And who can deny that the handling of the population problem would be much simpler if there were a better understanding of the reasons for the continuing increase of the population as well as better means of conveying simple information about agriculture and physiology to large numbers of badly educated people? In the same way, modern industrial techniques which could theoretically bring prosperity to impoverished people are often inadequately applied because those most in need of them lack quite simple skills which may have no direct connexion with science as such. The frustrations which these circumstances create have helped to spur on what now seems to be a growing appreciation of the social sciences, and even if what may be called the hard scientists are not universally enthusiastic about this prospect, it is a great pity to postulate a gulf which does not exist between science and the social sciences.

All this suggests that Dr Leach may have overlooked some of the difficulties of the problems with which he dealt and some of the tentative solutions for them which are being developed. Nevertheless it is valuable that he has in several ways provided a reminder that in trying to estimate the directions in which society should be encouraged to make fuller use of technology, people should consider quite radical possibilities. In this sense it is useful to be reminded that conventional patterns of family life may be as much of a strain as a source of stability. Certainly the English seem to be as much attached to boarding schools as the Israelis are to kibbutzim, and both of these are devices for diminishing the interaction between parents and children. Whether it is as valuable for him to suggest that everybody should be compulsorily retired at 55 is quite a different matter—there are surely more subtle and less wasteful ways of making sure that young people are not kept perpetually in chains by their elders, and there is plenty of American experience to bear this out. But perhaps Dr Leach has been more concerned to stir things up than to suggest realistic solutions for the problems which concern him. As a gadfly he has succeeded well enough, but it is unfortunate that in the process he has helped to encourage the view that there is somehow an inherent conflict between the interests of scientists and those of society.

Does the Past predict the Future?

THE conventional exercise of trying to decide what features of the past year have been most memorable is complicated, as far as science is concerned, by the fact that a year is altogether too short a time scale. In politics, momentous events can be contained entirely within a year. But discoveries in science are hardly ever as unexpected and unpredictable as are external events. A meaningful summary of past events would ideally be spread over a period more like three years than one. But, that said, there is some virtue in trying to make a list of what has happened in the year now nearly finished, if only for the sake of being more able to anticipate what is likely to happen next.

In this connexion, it is plainly important that a great deal has happened in the past few months to suggest that problems of cosmology are coming to the boil. The discovery in the past two years of what seems to be a cosmic microwave background has, of course, been a great spur to speculation about the origin and evolution of the universe. It is no doubt significant that this has now led to a renewal of interest in the construction of cosmological models (see this issue, page 1297) and a concern for the correctness or

otherwise of the general theory of relativity. Nearer home, events have shown the value of geophysical methods of studying the continuing movement of portions of the Earth's crust (see, for example, this issue, page 1276). Magnetic anomalies have turned out to be valuable means of following the spreading of material outward from the oceanic ridges on to the floor of the deep oceans. It is easy to predict that oceanographers will now be more concerned than ever to be given opportunities for studying deep ocean sediments, but it is, of course, impossible to know in advance what they will learn from them. It is also worth noticing that the success of the particle accelerators in high-energy physics has given people a familiarity with the unstable particles of matter which could not have been guessed at even a year ago.

In the biological sciences, there is plainly a great future for the studies which have in the past year or so helped to define the molecular structure of the substances which are effective in immunology, particularly the immunoglobins. It remains, of course, to be seen how quickly this will lead to a description of the tertiary structure of these materials and thus to a detailed understanding in molecular terms of the interaction between antigens and antibodies. If anything, the experience of the past year, during which there has been some cheerful progress with the X-ray diffraction analysis of tertiary protein structure, suggests that there is an awkward step between the description of a tertiary structure and an understanding of how this influences its function. That said, there is no doubt that strictly practical considerations will spur on attempts to understand in greater detail the mechanism of the immune response.

The year past has seen a further refinement of the genetic code, and, although it is now probably fair to expect that powerful uses will be made of the theoretical structure which has been established in the past few years, only a rash man would predict just what these will be. The experiment in which Professor A. Kornberg was able to replicate in the laboratory an infectious viral DNA is as much a proof of the rudimentary state of DNA chemistry at present as of the more awesome possibilities to which his sponsors at the National Institutes of Health gave some publicity. But if molecular biologists have a hard road ahead, so too do those who now believe that neurophysiology will bring important benefits.

Technologists will not be the only ones to look forward with pleasure to the use of increasingly sophisticated computing machinery. Artificial intelligence may smack too much of science fiction, but the phrase does also accurately suggest the wealth of exciting possibilities now opening up. To begin with, at least, the interest of computing machines which are more than mere automatic abacuses is that they will sharpen the faculties not merely of those who design machines and programmes for them, but of all those with an interest in problems of an essentially analytical character. Who knows, for example, what will be the intellectual consequences of the interest of the machine designers in methods of pattern recognition? comparison, the development of computing machinery as such may be at present less spectacular, but that is only a relative judgment. The consequences of the continuing trend towards faster and smaller electronic components will also be considerable. By contrast, the excitement which there has often been in recent years about the promise of superconducting materials seems not to have been too vigorously sustained by the experience of the past year, and it will probably be a long time before they are used to any great extent in heavy electrical engineering in the commercial world as distinct from the high-energy physics laboratories. In much the same way, the interest of transport engineers in new devices for moving people from one place to another is likely to be most fruitful in suggesting ways in which transport networks may be constructed. On the experience of the past year, the design of new vehicles as such is likely to be much less productive.

If it is hard to predict particular developments in science or even accurately to assess the significance of events in the recent past, it is, however, possible and even instructive to pick out trends in what seems to

be the temper of science. In this sense, it is important that in the past year there has been a marked slackening of the enthusiasm of governments for the lavish support of scientific research and industrial development. In the United States, for example, it seems as if special historical factors such as the commitment in Vietnam have tightened purse-strings, but the chances are high that, even if it were not for historical circumstances like these, the rapid increase of the science budget in recent decades would by now have slackened. Much the same is true of the way that things have gone in Britain. Although it is at first sight tempting to link the slackening of the growth of the research budget to the continuing economic crisis, there is also a possibility that expenditure would have tailed off even if there had been no external shortage of funds. What seems to be happening is that governments and the scientific institutions responsible for planning strategies of research are more than ever anxious to find criteria for relating the cost of research to the potential benefits. In the long run this is a good development, but it is a great misfortune that the first result has been to reduce the sums being spent on educationally desirable objectives.

Curriculum Development

THE Nuffield Foundation Science Teaching Projects. which became administratively under Chelsea College-University of London in August, have now moved to the temporary quarters of the Centre for Science Education established by the college at Pulton Place, SW6 The director of the centre is to be Professor K. W. Keohane, recently appointed to the chair of science education in the university, who is also co-ordinator of the Nuffield Science Teaching Projects.

A grant of £5,000 per annum for two years has also been received from Charter Consolidation Ltd. for use with the project to enable a study to be made of the ways in which applications of science might be introduced into the Nuffield teaching materials at a level. Dr Mansell has been seconded from Hatfield College of Technology to work with Dr Van Praagh on this work during 1967 when the main emphasis will be on chemistry. Later, similar studies will be undertaken in physics.

Less to Spend

THERE seems very little danger that the first round of restrictions on the scale of public expenditure in Britain will seriously hamper the prosecution of important projects in research and development. Ever since the devaluation of sterling on November 14, it has been clear that the British Government would have to make considerable economies, and the new Chancellor of the Exchequer announced a few days before Christmas that a total of £71 million would be cut from the expenditure of the nationalized industries in the coming financial year. In practice, however, the collective expenditure of the nationalized industries is so great that £71 million is not an important sum. For many of the industries concerned, the reduction will be most simply obtained by better management—

the General Post Office, for example, hopes to save £11 million in the coming year by running down its stocks of supplies and by postponing the renewal of various kinds of ancillary equipment-motor vehicles, for example. The postponement of various items of capital expenditure is, however, the most favoured expedientthe railways, for example, will put off the start of the electrification of the line between London and Glasgow for a year, while the British Airports Authority will postpone its scheme for a helicopter terminal for a similar period. The Central Electricity Generating Board will probably take the opportunity afforded by the Government's request to reduce expenditure by £17 million to put off the scheme for building a power station at Seaton Carew in north-east England. In the past few months, there has been some dispute about the fuel to be used for this power station—coal, oil or nuclear power. Coal interests have been urging that it would be unseemly to burn anything but coal in a power station built on the edge of a coalfield, and there seemed at one time to be a possibility that the Prime Minister had given an undertaking that this point of view would not be overlooked. It would be understandable if the Central Electricity Generating Board welcomed the opportunity with which it has now been

Research is likely to be more directly affected by the request for a reduction of expenditure of £3 million in the budget of the Atomic Energy Authority than by any of the other measures, larger though they may have been, which were announced by the Chancellor of the Exchequer. It seems to have been decided that the chief reactor projects will not be affected, which is entirely sensible. It is, however, significant that the Atomic Energy Authority now considers that the Dragon reactor is somewhere near the top of this list, along with the advanced gas-cooled reactor and the fast reactor. Evidently there are now high hopes that the technology of the Dragon will help enormously with future development of the advanced gas-cooled reactor. But if most reactor projects are sacrosanct, it probably follows that the authority will have to look to its research establishments for economies. The trouble here is that most of what could be done to economize at Aldermaston would not count in the authority's favour because it is paid for out of the defence vote, while the fusion laboratory at Culham is already faced with the prospect of trimming its sails by 50 per cent over the next five years.

In the circumstances, it is perhaps inevitable that the main burden of the economies ahead will fall on the laboratory at Harwell. It may even be that the Chancellor of the Exchequer is hoping that the dilemma which he has created will persuade the Minister of Technology finally to decide what should be done about Harwell. His colleagues in the British Government—and certainly those outside who reckon to keep a watch on developments like these—will be hoping that the necessarily stop-gap reductions of expenditure now announced will quickly be followed by policy decisions which promise a more permanent reduction of the scale of government expenditure.

London Intelligences

THE Research and Intelligence Unit of the Greater London Council has now been in action for nearly a year, the director of the unit, Dr Bernard Benjamin, having been appointed in 1966. Two divisions of the unit—GLC Statistics, and Research, are well established and a third which will serve the London boroughs will begin work early in 1968. The work of the unit, with particular reference to the field of information and intelligence, was described in a paper by R. G Dunsmore and R. E. Fry at a recent meeting of the Institute of Information Scientists.

The Research and Intelligence Unit does not have complete responsibility for statistics and research in the GLC, for separate departments such as housing took them over between the setting up of the GLC in 1965 and the formation of the unit. The unit's job, among other things, is to co-ordinate such activities. Mr Fry quoted three other aspects of the original terms of reference of the unit that are particularly important, and discussed the actions taken by the unit in these directions. The purposes mentioned were the setting up of an information system, which would contain statistics for forecasting material trends, and the publishing of a regular series of London statistics.

With the wide range of activities of the GLC involving an annual budget of over £400 million, the unit had to decide what statistics would be most useful. The conclusion was reached that information is required to support the needs of strategic planning in the widest sense. The unit would be the only body within the GLC with a comprehensive view of information kept in the different departments, and because of this could advise on gaps, unnecessary overlaps, coding and classification. One working group that has been set up is seeking agreement between certain GLC departments and the London boroughs on standardization of units for statistical data on transport and land use.

As the clerk to the council, in whose department the unit is located, has recently been up-ranked to director-general, to be the GLC's principal adviser on policy, the unit will be in effect his co-ordinator.

Schools Council and A-Level

THE Schools Council has at last published the document which embodies its proposals for a new pattern for the sixth form curriculum (Some Further Proposals for Sixth Form Work, HMSO, 3s. 6d.). This document has already been circulated to universities and was indeed the subject of the discussion among representatives of the universities at a meeting of the Senate House of the University of London on November 17. The proposals have been circulated to universities by the Standing Conference on University Entrance. The first reaction of the universities at the meeting in November was one of hostility to the Schools Council's proposals, chiefly on the grounds that they do not cater adequately for the need for a broader curriculum in the sixth form. The matter is to be discussed more formally at another meeting in the new year, and the universities are hoping to give the Schools Council a formal reply at Easter or thereabouts. The chances are that the universities will suggest, through the standing conference, an alternative to the sixth form pattern suggested by the Schools Council which takes the form of a broader pattern of studies (see Nature, November 25, 1967).

The essence of the new proposals by the Schools Council, which are said to have evolved from the

previous proposals for a mixture of "major" and subjects in the sixth form, is that externally examined A-level subjects should be restricted to two, even for intending candidates for university entrance. In addition, the Schools Council proposes that there should be a number of "elective" courses designed by schools to reflect the interests of staff and students and able to support and sometimes complement the remainder of students' work in the sixth form. It is intended that elective subjects should be examined or assessed internally by the schools and not externally by the existing examinations boards. One feature of the proposals is that the Schools Council has outlined ways in which elective studies could form a part of the sixth form curriculum for students not bent on university entrance but who continued to follow courses at Ordinary level instead of at Advanced level. The Schools Council also emphasizes the need somehow to diminish the pressure of competition for university places and much of its concern is with the conditions on which universities may be prepared to give students suitable assurances.

The argument is sustained by statistics which illustrate the changing pattern of the sixth form in British secondary schools. For one thing, for example, the population in the sixth form is growing rapidly, at least as far as can be seen from the increase of the proportion of seventeen year olds staying on at school from 8·1 per cent in 1955 to 11·1 per cent in 1960 and 13·8 per cent in 1965. At the same time, the proportions of sixth formers not following A-level courses seem to be increasing—the Schools Council has been given access to figures collected by the Inner London Education Authority which show that non-A-level pupils in the first year of the sixth form accounted for 7 per cent of the age group in 1963 and 10·5 per cent in 1967, only four years later.

Mathematics for the Less Talented

MUCH of the current interest in the reform of the school curricula has been concerned with the more talented pupils. In mathematics, the range of experimentation in the United Kingdom is unprecedented, with four large projects in progress, and a number of smaller ones, but again there is a danger that the less talented pupil will be overlooked. The Schools Council has now produced a pamphlet-Mathematics for the Majority, by Mr Philip Floyd—which sets out to remedy the deficiency. (In the introduction he does point out that the Schools Mathematics Project is undertaking a revision of its texts to cater for the less talented, and that the Midlands Mathematical Experiment could be used for below average pupils by extending the time scale.)

The report begins by establishing the greatest limitation to progress—the dismal lack of mathematics teachers in the schools. Because this deficiency does not seem likely to be made good within the next few years, any scheme which is devised has to be appropriate to the teaching talent available—talent which does not always correlate closely with the actual mathematical ability of the teacher. The report suggests a variety of ways in which the interest of children can be sustained by relating the teaching of mathematics to things which they understand, and by the use of equipment—calculating machines, conic

sections, equipment for simple surveying—which can help to make mathematics seem less dry and theoretical. Collaboration between mathematics departments and departments of English, history, geography and science can also help to relate arithmetic to real life. The Stock Exchange, opinion polls, wages and systems of payment, old people's budgets, defence costs—all these can be incorporated into a general scheme which brings mathematics to life. "It might be said," Mr Floyd writes, "that this is, overall, very ordinary mathematics; but these are very ordinary children, and this is the world of mathematics they see around them." But schemes such as this, he emphasizes, do not close the door to the more imaginative mathematical world which the children do not see around them.

Fortunately, the adoption by a number of schools of the Mode II and Mode III forms of examination for the Certificate of Secondary Education enables much more freedom with syllabuses than would otherwise be possible. (In Mode II, the syllabus is determined within the school, but examined outside; in Mode III. the syllabus and the examination are both the responsibility of the school, subject to an external moderator.) This offers a real opportunity for variety, and Mr Floyd makes some suggestions—the mechanics of flight, a study of the computer, the construction of logical circuits, the study of gears, the mathematics of betting and gaming, more respectably called actuarial science. He also provides a series of charts which provide a basis for planning syllabuses. But the final word in the report goes to A. W. Whitehead—"The whole of mathematics consists in the organization of a series of aids to the imagination in the process of reasoning." Teachers, as well as pupils, need these aids to the imagination, Mr Floyd concludes.

Architects

TALKS are in progress between the Architectural Association and the Imperial College of Science and Technology over the proposed link-up, whereby the AA will become the fourth constituent college of Imperial College. To some, this statement might seem as old as the Albert Memorial, but at last it seems that light is beginning to dawn, and it is hoped that agreement will be reached early in the new year. The University Grants Committee, the third party in the discussions, has agreed to its part of the bargain, which is to provide a recurrent grant, as part of its allocation to Imperial College, for the running of the architectural school. A letter from Sir John Wolfenden to this effect, sent to the AA in August, broke through the deadlock that had been reached. Up to that point, the UGC had promised the grant only if the AA had enough money for the necessary new building in South Kensington, while the AA in its turn felt unable to raise the building money unless the recurrent grant was assured. Now that this part of the problem has been solved it remains to the AA and Imperial College to agree over the building funds. Once the merger has gone through, the AA will cease to be a private institution and will instead be financed by government money, In this way it will be the second private institution of any size that has joined the UGC fold, the other being the Institute of Estate and Farm Management which has just been incorporated into Reading University.

There may be other private institutes and research centres in Britain that are reflecting on the possibility of becoming part of a university, with the accompanying measurable benefit of government grants, but the UGC seems not anxious to encourage such unions at present, when funds are so limited. There are several architectural schools, for example, at present attached to local authority art colleges, which would dearly love to become university departments. The Leeds school is particularly keen on the idea, but has not so far had much joy from the UGC. When there is not enough money in the kitty to pay for expansion in existing university departments, it is natural that there is reluctance on the part of the UGC to take on extra establishments. When the choice lies between paying fees that would have come from other sources for existing students, and providing money for additional students, the UGC's policy is understandable.

Canadian Research Flourishes

The National Research Council of Canada has spent five times more on scholarships and research in the universities in the past ten years than in the previous forty years of its existence. According to the council's annual report, the sum spent on Canadian universities has risen even in this past decade from \$10.5 million in 1962 to more than \$35.5 million last year. Nearly half of this sum is spent on grants and equipment, and the report estimates that, on the average, each professor received \$6,400 for equipment last year, a thousand dollars more than two years ago. Expenditure on university research is expected to continue to increase.

In 1966, the council established post-industrial experience research fellowships of \$6,000, to allow engineers and scientists in industry a year for research in government or university laboratories. The scheme is to run for a trial period of two years, five fellows being elected in each year. This year, to celebrate its own golden jubilee and the centenary of Canadian confederation, the council has decided to set up a new group of scholarships. These will be awarded to graduates for research leading to doctorates in universities other than those from which they obtained their first degrees. It is hoped by this means to foster cultural exchange between the different regions of Canada, in the spirit of the centennial year,

Homeless Doctors

SINCE the University of St Andrews became independent of Dundee University in October this year, it has been impossible for St Andrews medical students to do their clinical training. Most have continued to

go to Dundee for this purpose.

On December 19, however, the university announced that a link-up had been established between St Andrews and the University of Manchester. From 1973 onwards, preclinical students at St Andrews will go to do their clinical training in hospitals in Manchester, at the United Manchester Hospitals, and also at Withington Hospital, which is being developed into a full teaching hospital. Students at St Andrews will study for three years in the faculty of science on an extended preclinical course leading to a BSc degree, before going to Manchester.

A number of medical schools were approached in the hope of finding accommodation and several were willing to take a few students. The agreement with Manchester, on the other hand, will take the whole output of premedical students. According to Professor A. E. Ritchie at St Andrews, the liaison committee which will operate the scheme will probably be made up of Professor A. C. P. Campbell, Dr F. B. Beswick and Mr A. R. Anscombe representing Manchester, and Professor G. R. Tristram, Professor A. E. Ritchie and Professor R. Walmsley representing St Andrews.

Training Manpower

Last week the Ministry of Labour announced a new scheme for the training of craft apprentices in the development areas. The scheme extends the range of training grants already made under the levy and grants system introduced by the Industrial Training Act of 1964. The new grants are of two distinct types; one will provide capital grants towards the cost of providing places for training off the job, and the other will reward-employers who take on additional trainees for on-the-job training.

The capital grants, the ministry explains, are intended to encourage the provision of places for training off the job. The ministry will agree with the training boards a standard capital cost for providing the premises and equipment for the training. The employers who provide the new premises will get a grant worth 60 per cent of the cost of providing the places. If the employer can increase the number of training places without building new premises, the grant will be 60 per cent of the costs incurred. Grants of similar scale will be given in industries where there is as yet no recognized form of training. The per capita grant is intended for industries where training is normally done on, rather than off, the job. Employers who make more places available for trainees will be entitled to grants equal to £100 for each additional trainee.

So far, the industrial training boards cover industries which employ over 10 million people, a figure which will soon be increased to 15 million when new boards, already announced, come into operation. Next year the ministry estimates that some £120 million will be distributed to individual firms as training grants. The ministry is keen to make the schemes known to more firms, and has produced a pamphlet—Assistance with Industrial Training in the Development Areas (HMSO)—which explains them.

British Aircraft

THE British Government is now the dominant force in British aviation. There is nothing new in this, of course, but the point has been hammered home with particular emphasis in recent months. First there was the decision to build London's third airport at Stansted, then the apparent dithering over the Concorde, finally the announcement that British Aircraft Corporation would not be allowed to build the BAC 2-11. All these are important commercial decisions, but only in the last is it easy to see why the Government acted as it did. Although BAC wanted to build the 2-11, and British European Airways wanted to fly it, nobody wanted to pay for it. According to Mr Crosland, the President of the Board of Trade, it would have cost £120 million

to develop, against a mere £15 million for the Trident 3b, the alternative aircraft. In the circumstances, it was obvious what the outcome would be:

Despite the cancellation, BAC seems to have plenty of work; for one thing, it will be responsible for the British end of the Concorde production. The BAC 1-11, the company hopes, will continue to sell for a good time yet, and there may still be a few orders for the VC 10 and the Lightning. And the news that the Trident 3b is to be developed is bound to be an encouragement to Hawker Siddeley, disappointed by the Government's refusal to sell Buccaneers and Nimrods to South Africa. BEA is expected to want about 40 Tridents, and there may be a few orders from elsewhere now the decision to go ahead has been taken. But BEA will only accept the aeroplane on sufferance, and presumably as collateral to a Government agreement to provide the corporation with a financial reconstruction along the same lines as that enjoyed by BOAC. This is because BEA believes that the Trident will be more expensive to fly than the alternatives, one of which is the Boeing 727-200.

The alarming feature of the situation is not that the Government now pays the piper—that is probably inescapable—but that it is calling such a peculiar medley of tunes. While the Board of Trade has been mulling over the 2-11, the Ministry of Technology has been lavishing its formidable enthusiasm on the European airbus, a collaborative project in which France, West Germany and Britain are involved. To judge by the published reactions of some of the airlines, the airbus is no more immediately attractive than the What the Government should now be asking itself is whether the 2-11 would have been more attractive clad in the guise of European collaboration. Looking at it another way, would the airbus have seemed so desirable if BAC had proposed to build it alone? 'And why should two projects which clearly influence each other be the responsibilities of separate ministries? There is a real danger that the worthwhile aim of European collaboration is being used to justify projects which cannot justify themselves. That kind of muddled thinking will serve nobody's purposes but those of the United States aircraft companies.

Fall-out over Britain

Three Chinese nuclear explosions have occurred since the last recorded measurements were made in the United Kingdom of fission products in rainwater and airborne dust. In addition, France tested several nuclear devices in the South Pacific between June 1966 and July 1967. But in spite of this the latest Atomic Energy Authority research group report, Radioactive Fallout in Air and Rain: Results to the Middle of 1967 (UKAEA, 7s.), shows that the concentration of long-lived fission products over the United Kingdom has continued to decrease.

Prepared by the Health Physics and Medical Division of the Atomic Energy Research Establishment in Harwell, Berkshire, the report describes methods of sampling and analysis which were used over the period January 1966—July 1967: the data have been tabulated and, where appropriate, have been presented in graphical form. Airborne dust was sampled at one metre above ground by passing appropriate quantities of air through cylindrical filters of esparto grass paper

at a number of stations in Britain, Gibraltar, Hong Kong, and Pretoria and Aspendale in Australia. Samples of rainwater were collected in polythene bottles, containing carrier solution to reduce loss by adsorption, at eight stations in Britain and twenty stations elsewhere. Individual activities were determined either by radiochemical methods or by gamma-ray spectrometry.

The mean deposition of Sr-90 in rainwater at Milford Haven for the first half of 1967 was found to be 50 per cent of that for the first half of 1966. About onetenth of the long-lived fall-out in early 1967 was attributed to the Chinese explosion of December 28. 1966: this increase was sustained for several months because debris had been injected into the stratosphere. No short-lived fission products, such as iodine-131 from the Chinese explosion of June 17, 1967, were detected in Britain although there is evidence of debris from this explosion in the autumn of 1967. It is interesting to note that plutonium-238 was released over the southern Indian Ocean in April 1964 when an American satellite containing a SNAP-9A power source of 17 KCi of Pu-238 failed to orbit. During the last few months of 1966, cumulative deposition of long-lived fission products was reduced for the first time as radioactive decay exceeded new deposition. In early 1967, however, deposition again slightly exceeded radioactive decay.

Partially-hearing Children

A SURVEY of the special arrangements made to help partially-hearing children has been published this week by the Department of Education and Science. In 1966 there were 162 units for such children in England and Wales, of which the survey, conducted by HM inspectors of schools and medical officers, has covered 74.

The units are attached to schools and their purpose is to enable partially-hearing children to join the ordinary classes as soon as they are capable of doing so. Great care must be exercised in selecting children for the units, because severely deaf or otherwise retarded children will hold back the progress of the others. The survey recommended that more careful attention should be paid to the criteria for selecting children for the units. Children should be seen to have the prospect of learning to speak in a natural way more by listening than by lip-reading, and the unit's teacher should be consulted before selection so as to ensure that the child does not present too heavy a load of additional handicaps.

The survey suggested that units functioned better when they were large enough to include more than one class and more than one teacher. Though most of the units inspected are well supplied with audio-visual equipment and other aids, it is surprising that there has so far been little serious development in the use of programmed instruction or film loops.

programmed instruction or film loops.

All teachers of partially-hearing children are suitably qualified as teachers of the deaf. The survey found little to criticize in the standard of instruction within the units and indeed commended the progress made, but it pointed out that teachers who devote all their time to the units are often unaware of, and tend to underestimate, the standards reached by normal children.

The encouraging tone of the survey is marred only by the widespread lack of understanding found to exist in parents' attitudes towards their children's social and educational handicap. The survey stresses that parents need guidance and support in helping them to accept that their child may not make normal progress without special assistance.

Water Development

In its annual report, whose principal conclusion is that Britain has too much water—not too little—the Water Resources Board gives details of some interesting research being carried out under its aegis. There has, for example, been a programme of research into the regulation of the river Dee. Work on the generation of synthetic river flow data has been in progress at the Water Research Association and Lancaster University, and mathematical models representing catchment response are being studied at Imperial College. At the same time, attention is being paid to the problems of fisheries in the river, and it is hoped to build a fish counting station with an experimental electric fish barrier.

Less progress has been made in investigations of artificial recharge as a means of augmenting resources, largely owing to lack of staff. The report suggests that, although desalination plants similar to those built and projected in the United States will not be profitable in Britain in the immediate future, there is sense in the use of flash distillation plants in conjunction with conventional surface reservoirs to meet intermittent excess demands. It is important, therefore, that operating experience of a multi-stage flash distillation plant should be obtained in Britain. The pilot electrodialysis plant in Essex for desalting brackish ground water from the chalk is now in operation, however, and there is a possibility that such a system could be used for reclamation of water from industrial and sewage effluents.

A most important part of the Water Resources Board's programme is the development of automatic hydrometric instrumentation. It is hoped that by mid-1968 equipment will be available for recording climatological and river water quality data on magnetic tape in such a way that the information can easily be fed into a computer. The board has negotiated with instrument manufacturers as a group, rather than individually, and feels sure that the advantages of this particular procedure have been significant. An ICT 1901(S) computer has very recently been acquired, and a team of staff to handle it recruited. The new computer section will serve all the divisions of the board. At present river flow data have been processed for river authorities, and the new computer will allow the service to be extended to cover climatic and other data.

The total expenditure of the board on research and on contributions for the support of university and river authority work was £212,500 last year.

Production in Japan

Japan is expected to overtake West Germany in the production of motor vehicles this year, and so become the second largest motor manufacturer in the world. More than three million cars will have been built, an increase of no less than 40 per cent since 1966. Nor will this rate of growth fall, for production in 1968 should easily exceed four million vehicles.

Japanese exports used to be thought of as imitative and voluminous. Japan's achievements in shipbuilding and light engineering have convinced Westerners that the first of these epithets is unjustified, but it would surprise many to know that Japan's exports in 1966 were little more than half those of Britain—\$8,450 m against \$14,000 m, at the old rate of exchange. But if those in the West have exaggerated Japan's export performance, they have paid little attention to her importance as a producer of goods, as the table shows.

		W. Ger	_		
	Japan	many	Britain	Franc	e Italy
Sulphuric acid	5-66	3.06	3.3	2.9	4.75 million tons
Synthetic	0-00	9-00	0.0	2.9	4.19 Hillion sons
fibres	1,098	1,025	846	475	650 million lb.
Steel	41	36	27	19	12.6 million tons
Motor					
vehicles	1.88	$2 \cdot 9$	$2 \cdot 2$	1.5	11.4 million
Electricity	180	172	148	101	82 thousand million units
TV sets	4.2	$2 \cdot 8$	1.6	1.25	1.2 million
Ships	5.4	1.02	1.07	0.48	0.44 million tons launched

Statistics of Industrial Production, 1965.

The foregoing table demonstrates the somewhat surprising fact that even in 1965, Japan was producing more steel, electricity, television sets, and, of course, ships than France and Italy combined, and that her output of synthetic fibres and motor vehicles was even then comparable with the combined totals of those two countries. It is interesting to reflect on the difference between the economic and political weights of the first four countries listed here. Japan's reliance on the United States as a trading partner precludes extravagant political gestures. Perhaps the next few years will see Japan rise to a diplomatic importance commensurate with her strength.

Pooling Ocean Resources

TWENTY-EIGHT nations have joined in a proposal to set up a United Nations committee to study the peaceful international exploitation of the ocean floors of the world: the United States is a sponsor of the proposal.

According to a draft resolution presented to the General Assembly's main political committee, the proposed committee will be required to conduct a survey of the past and present activities of the United Nations and its various agencies regarding the ocean floor and of existing international agreements concerning them; to summarize the scientific, economic, technical, legal and other problems which are involved in international use of underwater resources; and, finally, to suggest the practical means by which international co-operation could be promoted in the exploration, conservation and use of the ocean floor and its sub-soil.

The recommendation grew out of a debate on the subject in the political committee, and it was Malta which suggested that resources beneath the sea should be exploited for the benefit of all mankind. In deference to national claims of territorial waters, the draft resolution restricts its recommendations to the "sea bed and the ocean floor, and the sub-soil thereof, underlying the high seas beyond the limits of present national jurisdiction". Before the new committee can be set up, however, the draft resolution must

first be endorsed by the political committee and then by the General Assembly as a whole.

Marketing is King

THE British engineering industry must give greater attention to marketing. This was the message delivered by the managing director of Massey Ferguson (UK), Mr J. W. Beith, in his lecture last week to the Institute of Mechanical Engineers.

Of the 14,992 engineering establishments in Britain, six hundred, or 4 per cent, account for two-thirds of the industry's total exports. An NEDC report in 1965 indicated that the probable rate of return on new investments in the engineering industry has been between 6 and 8 per cent during a period when the acceptable break-even rate was regarded as 15 per cent. Figures such as these, and the high import levels of foreign machine tools, indicate that some manufacturers fail to exploit in the market place the undoubted technical expertise which they possess.

Marketing, Mr Beith declared, should be the paramount activity in a company's operations, and must antedate and determine even the discovery in the research laboratories. If a product is to be tailored to its market, the whole strategy of a firm must be oriented towards the complex of research and planning activities which constitute marketing. Market research includes studies of such factors as the political and economic influences on a market, the demographic trends, the distribution of incomes and expenditures, and the likely appeal of alternative products. These findings form the basis for market planning, the function of which is to specify the product which will most profitably meet the situation described by market research. Market planning defines the physical characteristics of the product, its price, utility and styling; only then can design and manufacture begin, and any afterthoughts will be increasingly expensive. The goal of market planning is to strike the best balance between minimizing unit production costs and maximizing market appeal.

"The future of large sectors of engineering production," Mr Beith said, "will be influenced by the impact of marketing on engineering firms, and by the changes which it will bring about within those firms." The increasing importance of marketing is likely to favour the large firm against the small and to lead to fewer and larger firms. But perhaps the greatest change as firms become more market oriented, Mr Beith suggests, is that engineers will be expected to work within the parameters of the marketing approach and to think in terms not of the product itself but of its marketability.

Parliament in Britain

Nuclear Power

ASKED what effect the proposed reductions in capital spending by the nationalized industries would have on the construction of nuclear power stations, Mr Richard Marsh, the Minister of Power, replied that the start of one power station would probably be deferred. (Written answer, December 18.) At question time on the following day, Mr Wedgwood Benn, the Minister of Technology, defended his decision to close the Culham Establishment, set up for research into the generation of electricity by means of fusion. He said that that

programme was well over the horizon, perhaps as much as 25 years ahead. As for the proposal, put to him by Mr David Price, that he transfer Culham from the Atomic Energy Authority to the Science Research Council, he said that work on astrophysics at Culham was to be undertaken by the SRC, and that he was taking Mr Price's proposals seriously.

Sonic Booms

THE subject of sonic booms came up in both written and oral questions on December 19. The Minister of State for the Ministry of Technology, Mr Stonehouse, said that no decision had been made about restrictions to be placed on the speed of the Concorde airliner over inhabited areas. He estimated that the total market for the aircraft would be reduced to 65 per cent if a ban were to be imposed on the making of supersonic booms overland. Mr Stonehouse went on to say that he did not think it would be wise to start international discussions on supersonic flight over land. Britain, he said, was in touch with France and the United States and would co-ordinate with them in any decision. Nobody could be certain about the characteristics of the bang from Concorde until the aircraft was flying, but there was a great deal that could be learned, and was being learned, from the intensive tests carried out in the United States. In written replies to questions put to him by members, Mr Stonehouse said that the Ministry of Technology would shortly issue a statement about the July sonic boom tests. Thirteen local authorities had commented on various aspects of these tests.

American Aircraft Imports

In a written answer, Mr Stonehouse gave figures for the trade in aircraft and space products between Britain and the United States in the first ten months of this year. Britain imported £64,541,000 worth of aircraft, exporting £37,645,000 worth to the US. Mr Stonehouse thought that the export prospects of the aircraft industry would be enhanced as a result of devaluation. A Procurement Committee had been established under the British National Export Council and the Confederation of British Industries with the object of securing orders within the aerospace and avionics fields. (Written answer, December 20.)

Civil Defence Warning System

LORD STONHAM, Minister of State, Home Office, in a debate in the House of Lords, gave details of the warning system which would be used to alert the civil population in the event of war. He claimed that the warning system was virtually instantaneous and nation-wide. There were two types of warning signal. The first was a siren similar to that used in the last war. The difference was that the system would now be operated centrally, and warning would be communicated within 30 seconds to 22,000 different points. Each warning point was equipped with a radiac survey meter and, in the event of a breakdown in the communication system, the warning point operator would sound a warning when fall-out registered on the survey meter reached 0.3 röntgens per hour. the actual fall-out would be sounded by maroon. Distribution of maroons would begin early next year. In addition, fall-out warnings would be given by the BBC's wartime broadcasting system, picked up by transistor radios. (Debate, civil defence warnings, December 19.)

NEWS AND VIEWS

New Hearts for Old

THE publicity which surrounded the Washkansky heart transplant operation in Cape Town has caused the blurring of some details and the exaggerated prominence of others. And the picture has not been clarified by the dispute between those who say the operation was premature and those who claim that Professor C. Barnard anticipated other similar operations only through the fortunate concurrence of a suitable donor and recipient.

The morality of the operation has several times been questioned, but more by way of hypothesis than accusation. It is hard to see what special ethical conundrums are raised by a heart transplant. The doctor who decides that a patient is sufficiently dead for him to remove the heart while it is still functional takes a difficult decision, but this problem is not new to medicine. There is no sharp dividing line between life and death, and assessment of the transition has always rested on a complex of factors, not all of which may be objective. The first heart transplant does not raise a new problem, it exacerbates an old one. By doing so, it may help to draw attention to what seems to be the best of all safeguards—that the recipients of an organ transplant and the potential donors should be cared for by different doctors.

The interests of the recipient also matter, but Washkansky was undoubtedly made aware of the experimental nature of the operation, and his immediate assent for it precludes any reasonable doubt of his willingness to take the chance. In general, however, there is a case for asking that transplant operations should be undertaken only when there is a reasonable prospect that they can materially improve the chances that a patient can expect to enjoy a substantial period of reasonable health. This kind of decision has long been familiar in the treatment of cancer. It does not mean that treatments cannot be given for the first time, but merely that the pace of innovation is contained.

Not only surgeons will want to move cautiously, however. It has often been supposed that once heart transplanting becomes a viable operation, hospitals will be overwhelmed with applicants and that whatever selection method is devised will be, at the least, invidious. But a heart transplant is unlikely ever to become a straightforward and routine operation, and for many years yet it will require a team of highly experienced doctors. Ordinary people are unlikely to be overjoyed at the prospect of having to live with somebody else's heart, at least for several years to come.

If the moral and social implications of the operation have been exaggerated, the medical ones have remained uncertain, largely because the problems of tissue-typing

are as yet unsolved. Professor Barnard and his team were confident that enough was known to justify the risks, and Washkansky's survival beyond the usual period of tissue rejection must to some extent support their assessment. Nonetheless, for all the splendid surmounting of technical difficulties, the operation was not in the event successful. The crucial test lay not in the transplant of the heart itself but in the treating of the patient's immune defences. The failure of the immune defences to combat the final pneumonia signified the failure of the operation. The moral, if there is one, is that there would be great profit in spending more effort and money on research in tissue typing than is at present being spent. This, in the long run, is how successful transplants will be made.

Isolation of Permeases

from a Correspondent

The permeases—carriers or transporters—were until recently merely hypothetical entities, invented by biochemists to account for the puzzling phenomenon of membrane transport. Yet one by one permeases are being isolated, characterized and even, in one case, crystallized (Science, 156, 1627; 1967). A permease, defined by its ability to catalyse transport across an intact cell membrane, cannot be directly assayed when the membrane is no longer present. All procedures for monitoring the isolation of permeases therefore make use of ancillary features of the transport process—in most cases the ability of the isolated molecule to bind its substrate. Thus treatment of Escherichia coli with osmotic shock liberates a galactose-binding protein (J. Biol. Chem., 242, 793; 1967) and addition of the purified protein to cells depleted of binder restores their ability to accumulate galactose.

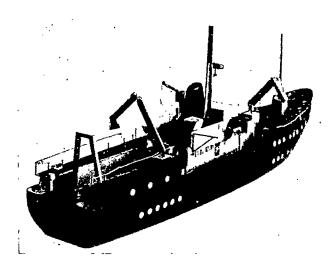

An experiment as striking as this has not yet been reported for the classic lactose permease of E. coli, but genetic evidence has now been obtained (Proc. US Nat. Acad. Sci., 57, 698; 1967) that the M-protein, a component of the lactose permease system, is indeed coded for by the permease gene. This gene maps between the β -galactosidase and galactoside transacetylase genes of the lactose operon. Binding of substrate to the permease is again the basis of the assay for the isolated M-protein, but the substrate is now used to protect an active centre against inactivation by N-ethyl maleimide, a reagent attacking thiol residues. The protected thiol is identified by its ability to react with additional, isotopically labelled, N-ethyl maleimide after the substrate is washed away. The M-protein is firmly bound to the spheroplast membrane, and released only by treatment with detergent. Permease negative mutants of E. coli do not synthesize the *M*-protein while in a temperature-sensitive revertant. Conditions which lead to the loss of permease activity in the intact cell lead also to a reduced yield of M-

protein. Mutants with deletion of the transacetylase gene are perfectly capable of forming M-protein. That the natural substrate, lactose, and also the excellent synthetic substrate thiomethylgalactoside do not block the inhibitory action of N-ethyl maleimide on the permease, and hence cannot be used in the labelling procedure, might reflect some property of the active centre of the protein rather than cast doubt on the correctness of its identification as the permease.

On the assumption that each molecule of M-protein possesses a single reactive thiol, a lower estimate of 9,000 permease sites per bacterium can be obtained. This compares well with the 3,000 sites per cell membrane shown by Kolber and Stein (Currents in Modern Biology, 1, 244; 1967) as being specifically labelled when the lactose operon is induced using thiomethylgalactoside. Extraction of cell membranes with sodium iodide solution liberates a labelled protein of molecular weight about 60,000. An earlier report of the labelling of cytoplasmic fraction apparently coded by the permease gene may represent some transient (nascent or degraded) form of the M-protein.

More Oceanography

The Natural Environment Research Council has not only approved the construction of the new oceanographic research vessel mentioned in its last annual report (see Nature, 216, 954; 1967), but it has also issued details of the specifications. The ship has been designed, by Yarrow-Admiralty Research Development, for operations in the regions of the Continental shelf and North Atlantic. The new ship will therefore be smaller than RRS Discovery, with a displacement of 1,000 tons and an overall length of 165 ft. She will be operated by the Scottish Marine Biology Association, and will be stationed at Oban, Argyll, where the S.M.B.A.'s new laboratories are at present being built, but she will be available to university workers.

Perhaps the most important innovation in the design of the vessel is the unorthodox stern, which allows the trawl to be brought in aft, instead of over the side as in most trawlers. Drag on towropes is a great inconvenience when delicate electronic equipment is being towed, partly because it is difficult to tow deep objects

close to the boat, and partly because of the induced vibration. The towing cables will therefore be faired to reduce turbulence, and this in turn has required the provision of a specially designed helical capstan. Steam turbines, not usually fitted in so small a ship, are also there to provide vibration-free movement.

Nine scientists will be accommodated on board, and they are apportioned a thousand square feet of laboratory space—a considerable area for so small a vessel. Some of this is to the side of the working deck at the stern, but all the laboratories are convenient of access to this deck, where the specimens are landed. Certain navigational features will doubtless further the scientific purposes of the ship: the tall sides at the stern, which will serve to head the bows into the wind and so reduce drifting, and the provision for bow thrusters to move the ship sideways.

Although it is expected that most of the ship's work will be biological, facilities have been provided for geological research. It will be possible, for example, to operate a deep sea geological corer, pneumatically powered, to take samples of rock at down to 1.500 metres. Trawling will be possible at a depth of 1.000 metres.

With this new hydrographic vessel about to be built -contracts will shortly be put out to tender, and the ship should be operating early in 1970—NERC will now be thinking about some of the other ships mentioned in its annual report. The largest of these, for the combined use of the universities and the Institute of Geological Sciences, would be among other things a mother ship for submersibles. The heavy lifting equipment needed for this task might also be useful for the operation of the deep sea geological sonar at present being developed by the National Institute of Oceanography. This piece of equipment, which goes by the alluring acronym of GLORIA (for Geological Long Range Inclined Asdic), uses a fan shaped beam 2.5° wide in the horizontal plane and 15° in the vertical plane to provide a picture of submarine geological strata over a range of ten miles. A model has been tested, and it is hoped to use the device itself from Discovery next April.

Autotropic Metabolism

from our Microbiology Correspondent

SOME micro-organisms are autotrophic: that is, they synthesize their cell components from simple chemical substances. Obligate autotrophs are limited to this way of life while facultative autotrophs are adaptable. Obligate autotrophs always require carbon dioxide as a source of carbon and either light or reduced inorganic compounds as a source of energy. Recent use of isotopic tracers has shown that, contrary to the pioneering studies of Winogradsky, certain organic compounds can be assimilated by obligate autotrophs: consequently the notion that these cells are impermeable to organic substances no longer provides a tenable hypothesis to account for obligate autotrophism.

Smith, London and Stanier (J. Bact., 94, 972; 1967) have examined an alternative explanation of this phenomenon, namely that obligate autotrophs are characterized by having defects in their intermediary metabolism which preclude the use of organic compounds as principal sources of carbon and energy. This

hypothesis was tested in obligate blue-green algae of species *Thiobacillus*, and two facultative autotrophs, *Hydrogenomonas eutropha* and *Thiobacillus intermedius*.

Acetate was most effectively assimilated by the bluegreen algae, but although it contributed up to 10 per cent of cellular carbon in these algae, the latter retained an overwhelming dependence on carbon dioxide for their carbon. In contrast, the facultative autotroph T. intermedius synthesized 40 to 88 per cent of its cell carbon from exogenous glucose, acetate, succinate or Incorporation of [14C]-acetate by the obligate autotrophs was almost entirely restricted to leucine and the glutamate group of amino-acids. This indicates an inability to convert acetate to oxaloacetate through a-ketoglutarate. In T. intermedius, however, carbon from acetate and pyruvate was incorporated into all of its amino-acids. The conclusions drawn from these incorporation experiments were confirmed by monitoring a number of enzymes in the TCA cycle and electron transport chain. Iso-citrate dehydrogenase was highly active in both obligate and facultative autotrophs, while malic and succinic dehydrogenases, although having similar distributions, had much lower activities in the obligate species. Significantly a-ketoglutarate dehydrogenase was not found in obligate species; thus, the accompanying low levels of malic and succinic enzymes indicate their purely biosynthetic role in an impaired TCA The obligate species also lacked reduced nicotinamide-adenine dinucleotide (NADH₂) oxidase activity.

The Berkeley group argue that the principal obstacle to a heterotrophic habit in obligate autotrophs is their incapacity to couple the catabolism of organic substrates to ATP production; a consequence of the lack of NADH₂ oxidase. The blue-green algae can maintain a balanced production of NADH₂ and ATP by appropriate regulation of the cyclic and non-cyclic photophosphorylations. In thiobacilli, the coupling of NAD reduction with the oxidation of sulphide, thiosulphate, tetra- and tri-thionate has not been observed, but such oxidations could instead be coupled to the reduction of a c-type cytochrome. The authors propose that generation of reduced pyridine nucleotide by an ATP-mediated reversal of electron transport may be a property of all chemoautotrophs with the exception of hydrogen bacteria. The NADH2 oxidase is probably essential for the metabolism of Hydrogenomonas, because the low potential of the $H_2: H^+$ couple requires a carrier at the potential level of pyridine nucleotides. This provides a cogent reason why hydrogen bacteria are the only facultative chemoautotrophs. The loss of NADH₂ oxidase by other chemoautotrophs would conserve the reducing power generated by reversed electron transport and, as biosynthetic demands can be met without the necessity of a complete TCA cycle, a-ketoglutarate dehydrogenase could have been the second enzyme to be eliminated in the evolution of obligate chemoautotrophs from heterotrophic ancestors.

Irradiating Cells

from our Cytogenetics Correspondent

RADIATION and many drugs which block DNA synthesis are used in cancer therapy, because they are able to

kill actively proliferating cells, although the way in which they kill cells is not at all clear. Some cells may be more sensitive than others because they spend more time in a particularly sensitive phase of the cell cycle. If this is so, which are the sensitive stages in the Tolmach and colleagues have recently reported experiments on this problem with human HeLa cells subjected to either X- or ultraviolet irradiation. They devised a technique (Pfeiffer and Tolmach, Nature, 213, 139; 1967) for selecting cells which are all in the same phase of the cell cycle. These cells then progress more or less synchronously through the subsequent phase of the cycle and so can be irradiated at definite phases and their sensitivity in these phases estimated. Djordjevic and Tolmach (Radiation Res., 32, 327; 1967) collected HeLa cells in the G_1 phase (before DNA synthesis, or the S phase) and irradiated them with X-rays. They found that fewer cells survived irradiation at the G_1 phase than if irradiated at either the S or G_2 (post $\overline{\text{DNA}}$ synthesis) phases. By contrast, sensitivity to ultraviolet irradiation increased towards the end of G_1 and reached a peak at mid-S. Cells irradiated with ultraviolet can enter S but the rate of DNA synthesis then slows down; previous work had shown that cells irradiated with a nearly comparable dose of X-rays at G_1 showed little reduction in the rate of DNA synthesis. The basis for these differences in sensitivity is unknown, but presumably biochemical events in cells at different phases have different responses to ultraviolet and X-rays, and damage to these events leads to cell death.

Ultraviolet radiation was found to stimulate a small amount of DNA synthesis in both G_1 and G_2 . Djordjevic and Tolmach suggest that this may represent the DNA synthesis needed to repair damage done by the ultraviolet. They found, however, that this "repair" synthesis was insensitive to inhibitors of DNA synthesis such as fluorodeoxyuridine (FUdR) and hydroxyurea (HU).

Weiss and Tolmach (Biophys. J., 7, 779; 1967) reported further experiments on the effects of X-rays on synchronized HeLa cells. They found that various inhibitors of DNA synthesis, including FUdR and HU, enhanced the killing effect of X-rays. example, many more cells were killed by X-irradiation at G_1 . HU was present at a concentration which prevents cell proliferation but is not toxic. Even if cells are not given HU immediately after irradiation at G_1 but a few hours later as the cells proceed into S, many more cells are killed than if given X-rays alone. But there is a lag period before the effect of HU is realized and this is roughly proportional to the time between irradiation and addition of HU. Again the biochemical basis for the enhancement of cell killing is unknown, but it is quite clear that HU increases the sensitivity of cells to X-rays and the cells remain susceptible to the influence of HU up to 12 hours after irradiation. Can cells and their contents be protected from radiation damage? When chromosomes replicate in the presence of bromodeoxyuridine (BUdR), this is taken into the chromosomes in place of thymidine. Subsequent ultraviolet irradiation causes many more breaks in the chromosomes containing BUdR than in those without it. Trosko and Brewen (Radiation Res., 32, 200; 1967) found that if cysteamine is present at the time of irradiation the number of breaks induced in chromosomes containing BUdR is very much reduced

but there is no effect on the number of breaks induced in chromosomes free of BUdR.

Repairing DNA

from our Molecular Genetics Correspondent

DURING the past six months an exciting addition to our knowledge of DNA synthesis has appeared, most of it from the work of four groups in the United States. These groups have discovered enzymes able to join a break in one strand of a DNA helix. This enzyme activity has been detected and the enzyme purified from E. coli and E. coli infected with T4 or T7 bacteriophages. The detection of this enzyme, which has been named a DNA sealase or DNA ligase, requires a rather sophisticated substrate. Basically two types of substrates have been used. Phage λ DNA molecules which are either hydrogen bonded to one another or hydrogen bonded to themselves into a circular DNA molecule can be covalently sealed giving covalent dimer DNA helices or covalently intact circular DNA helices. Alternatively, double-stranded DNA from a variety of sources can be "nicked" with an endonuclease, thereby producing a few single breaks in the helix. These breaks can be labelled specifically with radioactive phosphate using the enzyme polynucleotide kinase and y-labelled adenosine triphosphate, ATP. The breaks can then be rejoined by the ligase. Once the ligase has joined the labelled phosphate into the chain, the phosphate can no longer be removed from the DNA by the enzyme alkaline phosphatase.

The ligase isolated from *E. coli* has the surprising requirement for the co-factor diphosphopyridine nucleotide, DPN. The DPN has been shown to combine with the DNA ligase in the absence of DNA, forming an enzyme-adenylate complex and free nicotinamide nucleotide. This ligase-adenylate complex will now join a single-stranded break in a DNA helix, concomitantly releasing adenylic acid. The enzyme isolated from phage-infected cells requires ATP as a co-factor, and again forms an enzyme-adenylate complex in the absence of DNA, releasing pyrophosphate.

These enzymes, from whichever source they are isolated, apparently repair breaks in a DNA double helix only when the break has a 5' phosphate and a free 3' hydroxyl group in the break. It is likely that these enzymes play an important part in genetic recombination, the repair of radiation-induced damage, and DNA synthesis, but exactly how is unknown. (References: Gellert, M., Proc. Neurone Geometry

from our Neurophysiology Correspondent

FIVE papers in the current issue of the Journal of Neurophysiology deal with the location of excitatory

and inhibitory synapses on motoneurones. (Smith, Wuerker and Frank, J. Neurophysiol., 30, 1072-1096. 1967; Nelson and Frank, *ibid.*, 1097-1113; Burkem. ibid., 1114-1137; Rall, ibid., 1138-1168; Rall, Smith, Frank, Burke and Nelson, ibid., 1169-1194.) Rall has proposed a model for the contribution of dendritic potentials to postsynaptic excitation and inhibition measured at the motoneurone soma which is in several respects at variance with Eccles's model of the postsynaptic membrane. Eccles's model implies that to be effective in changing neuronal excitability a synapse must be located close to the neurone soma. Using this model Fatt showed how relatively ineffective synapses located on distant dendrites would be (Eccles, The Physiology of Synapses, Springer. Berlin, 1964). Several predictions can be made from the model: the maximum amplitude of a postsynaptic potential (PSP) should be linearly related to the postsynaptic membrane potential; there should be an equilibrium potential at which no postsynaptic currents would flow and no postsynaptic potential therefore be generated; and it should be possible to reverse the postsynaptic potential when the equilibrium potential is surpassed. These predictions are satisfied by the neuromuscular junction, which has become the "model synapse", but there are several discrepancies in motoneuronal behaviour. While inhibitory postsynaptic potentials (IPSPs) fit the Eccles model well. excitatory potentials (EPSPs) do not.

On the basis of their experiments, Rall and his colleagues contend that, while inhibitory synapses are located on, or close to, the motoneurone soma, excitatory synapses may be largely located on the dendrites. They measured changes of membrane impedance during PSPs and found that, while the majority of IPSPs were accompanied by impedance changes of the somatic membrane, EPSPs were accompanied by a variable degree of impedance change, less than half. in fact, producing a measurable change at the soma. If Eccles's model were correct, all PSPs should produce measurable impedance changes at the somatic membrane; however, if some excitatory synapses were dendritically located, then the impedance changes they produced would be extremely small or even too small to measure. Similarly, when the somatic membrane was hyperpolarized, the effect on EPSPs was extremely variable and was quite consistent with the suggestion that excitatory synapses are located on remote dendrites, making their EPSPs relatively immune to the effects of current passed through the somatic membrane. Furthermore, it seemed that EPSPs, unlike IPSPs. could have a quite complicated composition, reaching maxima and decaying over a wide range of times. This would be entirely consistent with the remote location of some dendritic synapses which would affect the somatic membrane electrotonically, and whose potentials would therefore be "smoothed" to a varying extent dependent on the area of neuronal membrane between the synapses and the soma.

All these experimental results fit Rall's theoretical calculations well, and are good evidence for his hypothesis that remotely located synapses contribute significantly to potentials measured at the motoneurone soma. This hypothesis has been developed for several years and is quite comprehensively discussed in one of Rall's earlier papers (Rall, Biophys. J., 2. 146-147; 1962).

Prejudices of Science Students

What does research mean to science undergraduates in universities? Are their attitudes towards industry based on prejudice, or on a rational assessment of where their best chances lie? A study by Mr Donald Hutchings of the University of Oxford Department of Education may help to provide the answers.

A survey carried out by the Oxford University Department of Education in 1963 showed that among scientific sixth formers, pure science has a prestige far greater than that of technology. Pure scientists, the schoolboys felt, led glamorous and exciting lives. They spent their time doing research work which was barely work at all, with the chance of making discoveries which would make them famous. Technologists, on the other hand, were drudges, less intelligent and less well paid than scientists, and often obliged to do boring work. Mr Donald Hutchings, who carried out the original survey, has now followed it up by examining the attitudes of science students in universities. How far are the original attitudes maintained? How do undergraduates make decisions, and on what are they based?

The results of the survey have now been published by the department as a book, The Science Undergraduate, a study of science students at five English universities. The evidence was gathered by interviews with more than 2,000 students of science and technology, at the Universities of Oxford, Cambridge, Leeds and Bradford, and at Imperial College, London. What emerges is a picture now becoming familiar in British education-of an undergraduate population only too eager to stay at university for a higher degree. A common remark, Mr Hutchings reports, was "If I get a good enough degree, I hope to stay on and do research". Almost three-quarters of the total sample felt this way, as Table 1 shows. But there were marked differences both between different subjects and between different universities. At Bradford, for example, a smaller percentage said that they wanted to study for doctorates, and only at Leeds did a significant number contemplate teaching. As Mr Hutchings points out, "It is disconcerting to note how pitifully few students intended to go for teaching: this may be understandable at Bradford, with its industrial emphasis, but if no more than the 4 or 5 per cent of scientists, including mathematicians, at Imperial College and at Oxford and Cambridge intend to teach, the serious shortage of science teachers is hardly likely to be alleviated".

Among pure scientists, by far the largest group was planning to stay on for a doctorate. But there were variations; comparatively few mathematicians, for example, chose a PhD rather than a master's degree; while 63 per cent of physicists were thinking in terms of a PhD, only 35 per cent of mathematicians had the same idea. And although the rather idealized view of research which Mr Hutchings had discovered among sixth formers had been modified, he reports that "it was heartening to see that the idealized picture of higher studies, and of research in particular, had not entirely disappeared". But third year students were at least beginning to show a more realistic view of their chances of being accepted; 46 per cent of first year undergraduates were thinking of

a PhD, but by the third year the proportion had fallen to 40 per cent.

Among the undergraduates interviewed there was a general unwillingness to go into industry, even to do research. A very large proportion said that they would prefer to stay on at university—only engineers viewed academic research with anything approaching suspicion. One engineer, Mr Hutchings reports, said that research "delays earning power", others thought that it led to pettiness and stuffiness, even triviality. The reluctance to leave university seems to be matched by a reluctance to consider even leaving the university of their first degree; Table 2 shows that 65 per cent of those contemplating PhD degrees wanted to stay at their own university. Only 5 per cent wanted to go abroad, a pattern repeated at all the British universities studied.

The effect of the undergraduate course itself was hard to detect, although an increasing number of undergraduate courses provide opportunities for students to do some research—at Oxford, in particular, the Chemistry and Metallurgy courses provide for a fourth year and a short research project. Mr Hutchings reports that this fourth year gave students an excellent opportunity of finding out whether they were really suited to research work.

The survey also enabled the variations in the background of the students to be examined. At Oxford and Cambridge—almost by definition—there were many more students from public schools, and no students at all from technical schools; at the other extreme, Bradford had as many as 28 per cent of students from technical schools in departments of applied science. But the remarkable feature (see Table 3) was that students from public schools showed a slight preference for the applied sciences (except at Bradford)

The greater glamour of pure science is shown in another way, by the proportion of the best pupils—judged admittedly by the crude criterion of A level marks—who choose

Table 3. PERCENTAGE OF STUDENTS FROM DIFFERENT TYPES OF SCHOOLS AT EACH INSTITUTION

		Gram- mar	Inde- pendent	Tech- nical	Other

pure science in preference to applied. Of pure scientists, 53·1 per cent had achieved a best A level mark of 75 per cent or over, while among applied scientists only 32·1 per cent had reached this standard. But in the range of marks from 71 to 75 per cent, candidates were divided almost equally between pure and applied science. The figures are interesting in another respect, Mr Hutchings says; they indicate that A levels have now become the necessary qualification for university entrance. Even at a technological university like Bradford, only 46 out of the 390 who were interviewed were admitted on Ordinary National Certificate or Diploma qualifications. And the figures suggest that HNC and ONC are now in full retreat as a means of entry; at Bradford, only 9 per cent of first year students had come in by this route, compared with 18 per cent of final year students.

Most of the students at Oxford and Cambridge were there by choice, Mr Hutchings reports. Among engineers at Cambridge, no less than 96 per cent had made it their first choice, and 82.6 per cent of pure scientists at Oxford had made it their first choice. Despite this, Oxford does not seem a particularly popular choice for science—only 3 per cent of those who did not get their first choice would have preferred Oxford, compared with 24 per cent who would have preferred Cambridge. Of the 128 students who were at Imperial College by second choice, Mr Hutchings says, 64 per cent would have preferred Cambridge. But Leeds shows a completely different result—only 4 per cent of those at Leeds by second choice would have preferred Cambridge, but 70 per cent preferred other principal universities as their first choice. The students were also asked why they chose the universities they did. At Oxford and Cambridge, the reputation of the university and recommendations from school seem to have been the important criteria, with the reputation of the particular department coming in down the list. In contrast, students at Leeds said that the reputation of the department was the most important criterion, and students at Bradford named particular types of course—normally a sandwich course with an industrial bias. Nearness to home seems not to have been important.

Some doubts intrude into the estimates given by students for hours of private study. At Oxford and Cambridge, where private study is expected of students, 45 per cent said that they did more than 20 hours a week. Elsewhere, in universities where lectures and formal instruction tend to take up more of the working day, estimates were lower, with the largest group—about a third of the students interviewed—saying that they spent between 11 and 15 hours a week working privately. As for vacations, Oxford and Cambridge students claimed to work harder than others. A hard core of 4 per cent denied doing any academic work at all in the vacation, but 40 per cent said they worked for about half the vacation, and 10 per cent stretched credibility by claiming to work for nearly all the vacation. In contrast, at Bradford 50 per cent said that they did very little, and 21 per cent that they did none at all. Oxford and Cambridge students spent less time in lectures than others-Bradford was notable in that 60 per cent of the students spent between 10 and 15 hours a week in lectures. And only 1 per cent of the students at Bradford were spending no time at all in the laboratory, against 32 per cent at Oxford and Cambridge. Practical work, in fact, was not highly regarded by the sample—only about 10 per cent thought it was the most helpful form of instruction (see Table 4). As for the form of instruction found least helpful (Table 5), Oxford and Cambridge students were particularly sceptical of the value of lectures. Apart from this, most students found little difference between different forms of instruc-This, Mr Hutchings comments, indicates a high degree of complaisance on the part of present university science students.

A similar attitude is hinted at in the answers given about research interests. "The most striking single fact

to emerge from the student's interviews was the almost complete lack of ideas about future postgraduate research," Mr Hutchings writes. Only 2.5 per cent of the students who firmly intended to do research had any idea what the topic would be; 43 per cent had no idea at all. Few students had considered the possibility of working in a field other than their main university subject, although a large proportion of pure science students were expecting to do applied research. If this is so, why did so many of the students want to do a further degree? The answers, Mr Hutchings says, divide into two categories, "idealized" and "mercenary". Table 6 shows the proportions falling into these two groups. Even among the mercenary answers, Mr Hutchings reports that few seemed very hard headed about salaries, although one engineer put it nicely by saying "Let's face it, a PhD is a good meal ticket". Although students were vague about the salaries they could expect, with a few taking a very pessimistic view of their chances, most said that they were more concerned with responsibility than with money.

Three-quarters of the students questioned said that they intended to work abroad at some time in their career. The majority thought that work overseas was a vital part of their training, as well as being interesting and desirable.

The Change to Metric Units

The British Government seems to be making rapid progress in its attempts to convert British institutions to the SI version of the metric system.

THE Government of France may say that the United Kingdom is not yet ready for membership of the European Economic Community, and there may be some truth in that. But there now seems every prospect that most British institutions will have changed over to a particularly pure form of the metric system by the mid-seventies. For better or worse, the days of the rod, pole and perch are numbered. What has happened may be counted as a cheerful victory for the campaign which some departments of the British Government, particularly the Ministry of Technology and the Board of Trade, have been conducting in the past few years.

The starting point for most of what has happened recently seems to have been the recognition by British industry and by the British Government, more or less at the time of the first negotiations for membership of the EEC in 1962, that a full-blooded adoption of a thoroughgoing metric system would be a slow process. By 1964, the Federation of British Industry (now the Confederation of British Industry) formally urged the Government to make preparations for what has since become known as metrication. On May 24, 1965, the British Government gave the project its blessing, and the President of the Board of Trade allowed himself to hope that the change would have been completed by 1975 or thereabouts. Since 1966, the Ministry of Technology has been chiefly responsible for encouraging the adoption of the change, chiefly through the Standing Joint Committee on Metrication under Mr A. H. A. Wynn, formerly chief scientist at the National Coal Board.

The British Government's success so far is quite considerable. Manufacturers are impelled along by the recognition that roughly half of the goods exported from Britain now go to countries in which metric systems of measurement are in use. The British construction industry announced its intention of adopting metric measurements at the beginning of 1967, and there are good reasons to expect that other sectors of industry will quickly follow suit. There have also been some modest successes in the field of education. The Council of Engineering Institutions has, for example, already decided that examinations held under its auspices shall rely exclusively on metric units in 1971 and thereafter. The Oxford and Cambridge Schools Examination Board has come to a similar decision about examination papers in physics at advanced level. Then, as reported in this journal two weeks ago, a group of editors of scientific journals brought together by the Royal Society has settled for the uniform and rapid adoption of metric units in the years immediately ahead.

Whether the trend towards metrication will go as far and as quickly as the Ministry of Technology would like to see remains, of course, to be determined. It may well be significant that the Confederation of British Industry has awakened, rather late in the day, to the fact that the distributive trades seem to be lagging behind the manufacturers in their readiness to adopt a metric system. Plainly it will be a great inconvenience if retailers insist on selling sugar by the pound and cloth by the yard when manufacturers have already been converted to kilograms and metres, but the distributive trades will probably be quick to point out that there is still a sense in which the customer must be considered to be right, and, that if people want to go on buying sugar by the pound, shop-

keepers have a duty to supply them with suitable packages. Because there are at present no plans for legislation to enforce a metric system, the Ministry of Technology must obviously prepare itself for a great deal of vigorous propaganda in a wider circle than that which is occupied by the manufacturers and the scientific journals.

In this connexion, the details of the metric system on which the Ministry of Technology has set its heart call out for more detailed attention. Metrication is more of a slogan than a specification of which of several versions of a metric system is to be introduced. The British Government is working for acceptance of the set of metric rules known as SI (which is an abbreviation of système internationale) promulgated by the meeting in 1954 of the Conference Générale des Poids et Mesures. This in turn is an elaboration of the MKS system, or of the MKSA (Giorgi) system. Altogether there are six basic quantities for length (m), mass (kg), time (s), electric current (A), thermodynamic temperature (°K) and light intensity (cd). To the metricians, the great virtue of SI units is that the system which they form is coherent. In other words, units of derived quantities follow directly from units of the fundamental quantities. Thus surface tension (expressed as force per unit length) is properly measured in units of newtons per metre. (The use of the newton as the unit of force is, of course, also consistent with the SI system as with the MKS system which is a sufficient specification of dynamical properties, so that one newton is equivalent to 100,000 dynes or to rather less than a quarter of a pound-weight.)

The SI system has also codified the rules for forming multiples and submultiples of the basic units. Briefly, multiple or fractional units which are not related to the basic units by factors of a power of a thousand are discouraged. This means that the centimetre is less well favoured than the millimetre as a measure of length, although it seems to be quite widely recognized that several years will pass before the centimetre is altogether banished. What will happen to the angstrom is less clear—the affection of X-ray crystallographers and chemists may be too strong for the SI system to prevail. Engineers are also putting up a strong fight against the Newton per square metre as a unit of pressure. (It is in any case agreed that the bar should remain for the time being.)

The system is summarized conveniently by the document prepared by the Royal Society's working party on metrication under Professor James Lighthill. This will be published early in 1968. A draft of that text follows below.

THE Royal Society Conference of Editors, after considering the part that scientific journals can play in connexion with the Government's policy of promoting the general adoption of the metric system in Britain, makes two main recommendations:

1. That the system of units known as SI should be adopted in all scientific and technical journals.

2. That, in order to keep to a minimum the difficulties which will inevitably arise during the period of transition, the change-over should be effected as quickly as possible.

SI (which is the abbreviation in many languages for Système International d'Unités) is an extension and

refinement of the traditional metric system. It embodies features which make it logically superior to any other system as well as practically more convenient: it is rational, coherent and comprehensive.

The metric system, which had spread to several countries in the aftermath of the French Revolution, began to be adopted in scientific work in Britain in the last quarter of the nineteenth century. Its use extended more and more widely, although a few branches of science remain where Imperial units have continued to predominate. It is fortunate that now that the time has come to discard completely the time-honoured native units (which are not without their advantages), there is to hand a fully developed International System to take their place. Over the years much thought has been given to extending and improving the metric system until finally in 1960 the Conference Générale des Poids et Mesures, the body responsible for maintaining standards of measurements (of which the U.K. is an active participant), formally approved SI. Already nearly thirty countries have decided to make it the only legally accepted system and it is clearly destined to become the universal currency of science and commerce. In many spheres in the U.K. (schools, universities, industry) the adoption of SI is being actively encouraged. The Conference of Editors is anxious that the journals devoted to science and engineering should seize the opportunity of playing a crucial part in helping to end the confusion and wastefulness (both mental and material) resulting from the present multiplicity of units.

The main features of SI are as follows:

1. There are six basic units (see below), the metre and kilogramme taking the place of the centimetre and gramme of the old metric system.

2. The unit of force, the newton (kg m s⁻²), is independent of the Earth's gravitation, and the often confusing introduction, in some branches of science and technology, of g into equations is no longer necessary.

3. The unit of energy in all forms is the joule (newton \times metre), and of power the joule per second (watt); thus the variously defined calories, together with the kilowatt hour, the B.t.u. and the horsepower, are all superseded.
4. "Electrostatic" and "electromagnetic" units are

replaced by SI electrical units.

5. Multiples of units are normally to be restricted to steps of a thousand and similarly fractions to steps of a thou-

Lists of the basic SI units follow, as well as lists of some derived SI units, of compatible units, and also examples of units which run counter to SI the use of which is accordingly to be actively discouraged. Also listed are the names and symbols of the prefixes representing numerical factors: these are both convenient in obviating the need to write large numbers of zeros or in some instances high powers of 10, and also helpful in establishing familiarity with the numerical framework of modern science. It will be noted that the recommended prefixes are limited to $10\pm 3n$.

The rate of the change-over towards complete metrication will vary from journal to journal, depending on the subjects covered and the extent to which the metric system already holds sway. In certain branches of science and engineering editors may decide to proceed to their target along the following route (with equivalent values given in parentheses):

$$\begin{array}{ccc} \text{non-metric (SI)} {\rightarrow} \text{SI (non-metric)} {\rightarrow} \text{SI} \\ \text{(stage II)} & \text{(stage III)} \end{array}$$

In some branches full metrication will have to wait upon the installation of metric machinery and equipment. (Where measurements are expressed in the form of instrument readings they should be so recorded and a conversion factor quoted.) In many journals, on the other hand, change-over to SI units can be achieved in one step, and the experience of some editors and authors where changes have already been introduced is that such changes are

more readily accepted than would have been supposed before their introduction.

Basic SI Units

physical quantity	name of unit	symbol for unit
length	\mathbf{metre}	m
mass	kilogramme	kg
time	second	S
electric current	ampere	A
thermodynamic temperature	degree Kelvin	$^{\circ}\mathrm{K}$

Organochlorine Pesticides in Seals and Porpoises

A. V. HOLDEN K. MARSDEN

Freshwater Fisheries Laboratory, Pitlochry, Perthshire

numerator of an expression.

Seals and porpoises in Scotland and Canada, far from the sites of application of pesticides, can accumulate high concentrations of residues in their blubber. These chemicals are spreading through the long food chain which ends with seals and porpoises and obviously cannot be confined to their place of discharge.

pound (f)/sq.in.

THE presence of organochlorine residues in marine life in many areas of the world, including the Antarctic, has been reported recently^{1,2}. In British waters the accumulation of residue in the eggs of sea birds³ and the process of concentration of pesticides through certain food chains in the marine environment⁴ have been studied. Analyses of various species of marine fish and mamnals from Scottish waters during the past 5 years^{5,6} have shown that organochlorine residues are now a normal occurrence, the highest concentrations being found in organs or tissues with the highest lipid content. Thus the muscle tissue of salmonids, the livers of cod and the blubber of seals act as storage sites for these residues.

The aquatic mammals, such as whales, seals and porpoises, have a relatively high proportion of the body weight in the form of subcutaneous fat (blubber). Seals feed chiefly on gadoids and salmonids, and porpoises chiefly on small gadoids and clupeoids. The process of concentration of pesticides through their food chain might be expected to result in high pesticide levels in the fat of these mammals, and samples analysed at this laboratory confirm this expectation. In recent years, specimens of the grey seal (Halichoerus grypus), common seal (Phoca vitulina) and porpoise (*Phocaena phocaena*) have been sampled from the coasts of Scotland. Samples of blubber were available for all the specimens examined, and in a few cases other organs were also available. As well as recognized pesticide residues, other electron-capturing substances have been detected by gas-liquid chromatography and, in order to establish whether such substances are as widely distributed as the pesticides, blubber samples from grey seals and harp seals (*Phoca groenlandica*) on the Canadian Atlantic coast have also been examined and the results of these analyses are reported here. Examination of samples of seal blubber from other areas is continuing in order to assess the variation between different regions of the marine environment.

All tissue samples from Scottish waters were frozen at -18° C until required for analysis. The Canadian samples were preserved in 10 per cent formalin, which showed no evidence of any influence on the analytical procedure, and in this and other cases involving fish it has not affected the efficiency of recovery of pesticide residues. Aliquots of the samples (5 g) were ground to a powder with anhydrous crystalline sodium sulphate (AR grade) and extracted in a Soxhlet apparatus with redistilled AR grade n-hexane (previously tested and found to be free of electron-capturing materials by gas chromatography). The hexane extracts were made up to 100 ml. and 25 ml. aliquots were subjected to clean-up by the hexane-dimethylformamide partition method of de Faubert Maunder et al., followed by column clean-up using alumina containing 5 per cent water. The loss of pesticide residues from fat extracts so treated is up to 20 per cent, but, as is customary in pesticide analyses, no correction has been made for such losses in the results presented here.

The cleaned-up hexane extracts were analysed by gasliquid chromatography on a Varian 'Aerograph 205-2B' instrument employing two glass columns 5 ft. long $\times \frac{1}{8}$ in. outer diameter. One column was packed with 'Chromosorb WAW/DMCS 80–100' mesh coated with 10 per cent

DC-200 silicone oil, and the other with the same support coated with 5 per cent DC-200 + 7·5 per cent QF-1 fluorosilicone. The oven temperature was 200° C, the nitrogen gas flow 50 ml./min and the column resolution for dieldrin equivalent to 1,600 theoretical plates. There was no significant degradation of DDT on the columns. While complete separation of the common pesticide residues is possible on one or other of these columns, interference by polychlorinated biphenyl (PCB) residues8,9 with p,p'-TDE and p,p'-DDT peaks necessitated a further analytical stage. Aliquots (5 ml.) of some of the extracts were evaporated to dryness in a stream of cold filtered air, and the residues refluxed with 2 ml. of 2.5 per cent alcoholic potassium hydroxide for 15 min on a warm water-bath. After cooling, 5 ml. of n-hexane was added, with mixing, followed by 40 ml. of 2 per cent sodium sulphate solution. The supernatant hexane layer was then analysed by gas-liquid chromatography. By this technique, quantitative conversion of p,p'-DDT to p,p'-DDE, and of p,p'-TDE to p,p'-MDE (=DDMU), is obtained, and the conversion products confirm the identity of the original residues. The residual peaks in the p,p'-DDT and p,p'-TDE positions, where present, can be subtracted from the values of the pesticides originally determined in these positions. Hydrolysis also destroys α and γ-BHC, where present, but polychlorinated biphenyls are un-A cyanosilicone (XE-60) column¹⁰ has also been used to separate p,p'-DDT and p,p'-TDE from PCB interference, confirming the latter.

The principal pesticide residues found in all samples examined were those of the DDT group, with dieldrin Canadian seals contained in much smaller quantities. lower concentrations of dieldrin than Scottish seals, while Scottish porpoises contained remarkably high concentrations of all pesticide residues (see Table 1). Interference on the DC-200 silicone column in the p,p'-TDE position caused by a non-hydrolysable residue was responsible for about 25 per cent of the total estimated p,p'-TDE in the Canadian and Scottish samples examined. In the p,p'-DDT position, the non-hydrolysable residue constituted about 10 per cent in the Canadian samples and about 30 per cent in the Scottish samples examined for this interference, the total amount of non-hydrolysable material being smaller in the Canadian samples. values in Table 1 have not been corrected for this interference, for only a proportion of the samples were hydrolysed. Results from the various species of seals were not noticeably different in a given area, and have been combined in Table 1.

*	•	/	/	,	\

Contamination by pesticides is greater in the seals on the east coast of Scotland (taken in an area roughly from Aberdeen to the Tay estuary) than in specimens from the west and north coasts, including the Orkney Islands. Seal pups from the Orkney and Harris (west coast) breeding grounds contained only slightly lower residues than adults from the same areas. By comparison, the Canadian samples from the Magdalen Islands (Gulf of St. Lawrence) contained very low levels of both dieldrin and the DDT group, while seals from the Cabot Straits (Gulf of St. Lawrence) contained little dieldrin but higher DDT group residues, similar to those of Scottish seals. Of the few porpoises examined, that from Orkney was the least contaminated, but the three taken on the east coast of Scotland had markedly higher contents of all the residues measured. One specimen contained a total residue concentration (dieldrin and DDT group) of 73·3 p.p.m. Analyses of a few tissues other than the blubber have been made, but concentrations in the blubber have always been found to be the highest (Table 2). Concentrations in other tissues seem likely to be consistent with their lower lipid contents.

Table 2.	TOTAL DDT	CONCENTR.	ATIONS (p.	.p.m.) IN V	ARIOUS T	ISSUES
Sample	Blubber	Liver	Brain	Kidney	Spleen	Muscle
Grey seal	5.8	0.77	0.26		*****	
Grey seal	9-2	0.36	0.15	*****		
Grey seal	14.8	0-97	0.24		0.53	
Grey seal	8.4	0.46	0-17		0.13	
Grey seal	2.4	0.11	0.07		0.06	-
Porpoise	3.8	0.58	0.02	0.04	0.10	0.56

The proportion of blubber extractable by hexane was determined for some samples. Values ranged from 72 to 86 per cent (mean 80 per cent) for the Canadian seals, and from 88 to 98 per cent (mean 93 per cent) for Scottish seals samples on the breeding grounds off the west coast. (Values for other seal samples were not estimated.) Concentrations of pesticides in terms of extractable fat for these samples would thus be up to 40 per cent greater than the values in Table 1, but the general comparison is not significantly affected. The lower extractable fat values for the Canadian samples may possibly be a result of being preserved in formalin.

Concentrations of pesticide residues in the extractable fat of various organs and tissues of one porpoise show an important relationship (Table 3). While the concentrations of the DDT group in the original tissues vary widely, those expressed in terms of extractable fat are in much closer agreement, with the sole exception of the brain. A similar anomaly for tissues of trout was described by Holden¹¹. It seems likely that a large proportion of the lipid fraction of the brain may not contain pesticides, and the brain lipid composition is known to differ considerably from that of depot fat.

Table 3. CONCENTRAT	ions of t	OTAL DD	r (p.p.m.)	IN TISSU	ES OF A P	DRPOISE
Tissue or organ	Blubber	Muscle	Liver	Spleen	Kidney	Brain
Concentration in tissue Percentage extract-	3·8 67 · 0	0·56 6·1	0·58 13·2	0·12 5·1	1·4 1·4	0·02 8·3
able fat Concentration in extractable fat	5-6	9-2	4.8	2.4	2.9	0-27

The unidentified peaks on the chromatograms seem to be similar to those produced by polychlorinated biphenyls and, to enable comparison to be made, the ratios (Rx) of the retention times of all regularly occurring peaks (relative to dieldrin=100) have been calculated for the operating column temperature of 200°C, these values being temperature-dependent. The Rx values of PCB compounds from commercial PCB formulations were also determined for both types of column (Table 4). At least seven PCB-type peaks were found, including those which interfere with p,p'-TDE and p,p'-DDT. Heptachlor epoxide and p,p'-MDE could not be confirmed on both columns and are not therefore recorded.

The most significant aspect of the results is that, although seals and porpoises inhabit an environment far removed from the site of application or discharge of pesticides, they can contain much greater concentrations of dieldrin and DDT group residues than those recorded for most other species, including man. Robinson and Hunter¹² found a mean concentration of dieldrin of 0·22 p.p.m. (range 0·10–0·73 p.p.m.) and a mean total con-

centration of DDT of 4.0 p.p.m. (range 1.0-11.1 p.p.m.) in samples of human depot fat in England in 1964. No evidence of any significant change was found during 1962-65.

The seals and porpoises from the east coast of Scotland were usually more seriously contaminated than those from the north and west coasts. This, at least in respect of seals, may be because, as is believed, the populations in the two areas come from different breeding sites. The seals south of Aberdeen breed principally on the Farne Islands, off the north-east coast of England, while the seals of north and west Scotland are primarily from the breeding grounds of the Orkney Islands in the north, and other islands off the west coast of Scotland. The sea off eastern Scotland is also likely to receive more contamination from estuarine discharges than that off north and west Scotland. Similarly, the two separate seal populations sampled off the east coast of Canada may inhabit areas with different levels of contamination. Pups contain pesticide residues in concentrations only slightly lower than in the parent population. Common seals in Holland have been found with concentrations of residue similar to those of seals on the Scottish east coast13.

While the residue concentrations in subcutaneous fat are high, those of other tissues and organs are found to be much lower. This suggests that there is no risk of physiological effects, unless the metabolism of much of the fat in times of stress leads to a considerable increase in the concentration of the residue in circulating lipids, and thus in residue concentrations in other organs or tissues.

Grey seals on the coast of the Scottish mainland feed primarily on salmon (Salmo salar) and cod (Gadus morrhua)14. The highest concentrations of pesticide in salmonids in the marine environment have so far been found in sea trout (S. trutta) on the east coast with up to 0.2 p.p.m. (dieldrin + total DDT) in muscle tissue15, and salmon from the same area would probably have similar contents. Cod examined from the east coast have contained up to 0.35 p.p.m. (dieldrin + total DDT) in muscle tissue (mean 0.12 p.p.m.) and from the west coast up to 0.56 p.p.m. (mean 0.22 p.p.m.), while cod livers contained up to 4.0 p.p.m. and 12.0 p.p.m., respectively. Grey seals are estimated to eat about 15 lb. of food daily, and thus an adult seal could consume its own weight in food in 20-30 days. Assuming a high proportion of the pesticide intake to be stored in body fat rather than to be excreted or metabolized, an increase of two orders of magnitude in pesticide concentration from food to body fat within a few years is feasible. This degree of accumulation of residue in an environment not deliberately contaminated, and in species ecologically far distant from the target organisms of persistent pesticides, underlines the impossibility of confining such chemicals to the areas of application.

We thank Dr B. B. Rae for obtaining the Scottish samples, and Dr C. J. Kerswill for the Canadian samples.

The North Pacific: an Example of Tectonics on a Sphere

D. P. McKENZIE R. L. PARKER

Institute of Geophysics and Planetary Physics, University of California at San Diego

Individual aseismic areas move as rigid plates on the surface of a sphere. Application of the Mercator projection to slip vectors shows that the paving stone theory of world tectonics is correct and applies to about a quarter of the Earth's surface.

THE linear magnetic anomalies1,2 which parallel all active ridges can only be produced by reversals of the Earth's magnetic field if the oceanic crust is formed close to the ridge axis³. Models⁴ have shown that the anomalies cannot be observed in the North Atlantic unless most dyke intrusion, and hence crustal production, occurs within 5 km of the ridge axis. The spreading sea floor³ then carries these anomalies for great horizontal distances with little if any deformation. The epicentres of earthquakes also accurately follow the axis and are offset with it by transform faults^{5,6}. The structure of island arcs is less clear, though the narrow band of shallow earthquakes suggests that crust is consumed along a linear feature.

These observations are explained if the sea floor spreads as a rigid plate, and interacts with other plates in seismically active regions which also show recent tectonic activity. For the purposes of this article, ridges and trenches are respectively defined as lines along which crust is produced and destroyed. They need not also be topographic features. Transform faults conserve crust and are lines of pure slip. They are always parallel, therefore, to the relative velocity vector between two plates—a most useful property. We have tested this paving stone theory of world tectonics in the North Pacific, where it works well. Less detailed studies of other regions also support the theory.

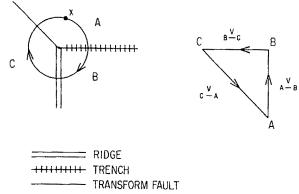

Fig. 1. The circuit and its vector diagram show how a ridge and a trench can meet to form a transform fault.

The movement of blocks on the surface of a sphere is easiest to understand in terms of rotations. Any plate can clearly be moved to a given position and orientation on a sphere by two successive rotations, one of which carries one point to its final position. a second about an axis through this point then produces the required orientation. These two rotations are equivalent to a single rotation about a different axis, and therefore any relative motion of two plates on the surface of a sphere is a rotation about some axis. This is Euler's theorem, and has been used to fit together the continents surrounding the Atlantic. If one of two plates is taken to be fixed, the movement of the other corresponds to a rotation about

some pole, and all relative velocity vectors between the two plates must lie along small circles or latitudes with respect to that pole. If these small circles cross the line of contact between the two plates, the line must be either a ridge or a trench depending on the sense of rotation. Neither of these structures conserves crust. If the line of contact is itself a small circle, then it is a transform fault. This property of transform faults is very useful in finding the pole position and is a consequence of the conservation of crust across them. There is no geometric reason why ridges or trenches should lie along longitudes with respect to the rotational pole and in general they do not do so. The pole position itself has no significance, it is merely a construction point. These remarks extend Wilson's concept of transform faults to motions on a sphere, the essential additional hypothesis being that individual aseismic areas move as rigid plates on the surface of a sphere.

There are several points on the surface of the Earth where three plates meet. At such points the relative motion of the plates is not completely arbitrary, because, given any two velocity vectors, the third can be determined. The method is easier to understand on a plane than on a sphere, and can be derived from the plane circuit in Fig. 1. Starting from a point x on A and moving clockwise, the relative velocity of B, $_{\lambda}v_{s}$ is in the direction AB in the vector diagram. Similarly the relative velocities $_{x}v_{o}$ and $_{v}v_{s}$ are represented by BC and CA. The vector diagram must close because the circuit returns to x. Thus:

$$_{\mathbf{A}}v_{\mathbf{B}} + _{\mathbf{B}}v_{\mathbf{c}} + _{\mathbf{c}}v_{\mathbf{A}} = 0 \qquad (1)$$

The usual rules for the construction of such triangles require three parameters to be known, of which at least one must be the length of a side, or spreading rate. Transform faults on both ridges and trenches are easy to recognize, and they determine the direction, but not the magnitude, of the relative velocities. The magnetic lineations are one method of obtaining $_{\rm B}v_{\rm c}$, though this value must be corrected for orientation unless the spreading is at right angles to the ridge. Then the triangle in Fig. 1 determines both $_{\rm a}v_{\rm a}$ and $_{\rm c}v_{\rm a}$. This method is probably most useful to determine the rate of crustul consumption by trenches. Equation (1) must be used with care, because it only applies rigorously to an infinitesimal circuit round a point where three (or more) plates meet. If the circuit is finite, the rotation of the plates also contributes to their relative velocity, and therefore these simple rules no longer apply.

Equation (1) is easily extended to the corresponding problem on a spherical surface because angular velocities behave like vectors.

$$_{A}\omega_{B} + _{B}\omega_{\sigma} + _{\sigma}\omega_{A} = 0 \tag{2}$$

The sign convention takes a rotation which is clockwisewhen looked at from the centre of the sphere to be a positive vector which is pointing outward along the rotation axis. By adding more terms, equation (2) can be extended to circuits crossing more than three plates and applies to all possible circuits on the surface. ω diagrams for three plates are no more difficult to construct than those for v, because the third vector must lie in the plane containing the other two. This result does not apply

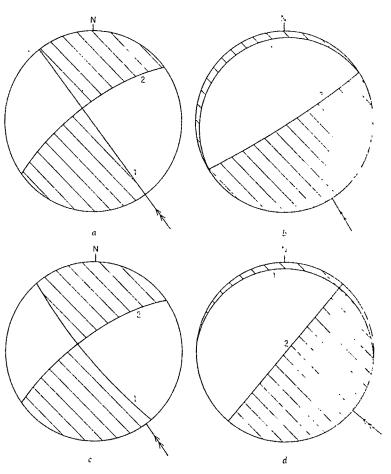

Fig. 2. Mechanism diagrams for four circum-pacific earthquakes. The lower half of the focal sphere is projected stereographically on to a horizontal surface, and the rarefraction quadrants are shaded. The horizontal projection of the slip vector in plane 1 is marked with a double arrow. (a) June 28, 1966, Parkfield¹⁵, strike slip. (b) September 4, 1964, Alaska¹⁶, overthrust. (c) June 14, 1962, Near and Aleutian Islands¹⁴, strike slip. (d) October 20, 1963, Kurile Islands¹⁷, overthrust.

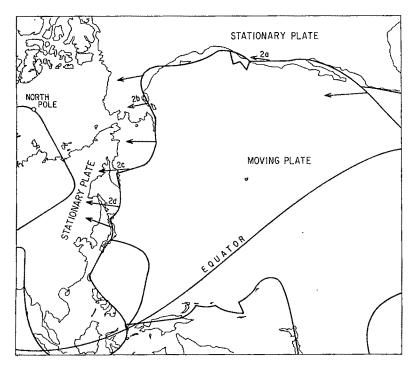

Fig. 3. A Mercator projection of the Pacific with a pole at 50° N., 85° W. The arrows show the direction of motion of the Pacific plate relative to that containing North America and Kamchatka. If both plates are rigid all slip vectors must be parallel with each other and with the upper and lower boundaries of the figure. Possible boundaries of other plates are sketched.

to diagrams for four or more plates, which are three dimensional and therefore less easy to draw.

These geometrical ideas can now be applied to the North Pacific. There are many fault plane solutions for earthquakes in the area, and these are used in a new way in order to determine the direction of the horizontal projection of the slip vector. Unlike the projection of the principal stress axes, that of the slip vector varies in a systematic manner over the entire region. This is clearly a consequence of spreading of the sea floor, which determines the relative motion, not the stress field.

The North Pacific was chosen for several reasons. The spreading rate from the East Pacific rise is the most rapid yet measured², and should therefore dominate any slight movements within the plate containing North America and Kamchatka¹⁰. The belt of earthquake epicentres which extends from the Gulf of California to Central Japan without any major branches¹⁰ suggests that the area contains only two principal plates. Also, the belt of seismic activity between them is one of the most active in the world and many fault plane solutions are available^{6,11-17}. It is an advantage that the trend of the belt which joins the two plates varies rapidly over short distances, because this illustrates the large variety of earthquake mechanisms which can result from a simple rotation (Fig. 2). It is also helpful that the outlines of the geology and topography of the sea floor are known.

Fault plane solutions which were obtained from the records of the world-wide network of standardized stations now give excellent and consistent results^{6,18}. The directions of principal stress axes, however, which were determined from first motions, vary widely over short distances (Fig. 2) and are therefore difficult to use directly. The concept of spreading of the sea floor suggests that the horizontal projection of the slip vector is more important than that of any of the stress axes, and Fig. 2 shows that this is indeed the case. The examples which are illustrated are stereographic projections of the radiation field in the lower hemisphere on to a horizontal plane¹⁶. The direction of the projection of the slip vector in plane one is obtained by adding or subtracting 90° from the strike of plane two

if the planes one and two are orthogonal. The slip directions which are shown give the motion of the oceanic plate relative to the plate containing North America and Kamchatka. For each case in Fig. 2 there are two possible slip directions, but, whereas one changes in direction slowly and systematically between Baja California and Japan, the other shows no consistency even for earthquakes in the same area. ambiguity is therefore unimportant in this case. If all the earthquakes between the Gulf of California and Japan are produced by a rotation of the Pacific plate relative to the continental one, any pair of widely spaced slip directions can be used to determine the pole of relative rotation. The two which are used here are the strike of the San Andreas between Parkfield and San Francisco, and the average slip vector of all the aftershocks in the Kodiak Island region16 of the 1964 Alaskan earthquake. A pole position of 50° N., 85° W. was obtained by construction on a sphere. If the paving stone theory applies, all slip vectors must be parallel to the latitudes which can be drawn with respect to this pole. Though this prediction could be tested by tabulating the disagreement with the observations, a simpler and more obvious test is to plot the slip vectors on a map of the world in Mercator projection, taking the

projection pole to be the rotation axis (Fig. 3). The Mercator projection has two advantages; it is conformal, which means that angles are locally preserved and slip vectors can be plotted directly, and also all small circles centred on the projection pole are parallel. Because the upper and lower boundaries of Fig. 3 are themselves small circles, the theory requires all slip vectors to be parallel both to each other and to the top and bottom. This prediction was tested on eighty published. Taket plane solutions for shallow earthquakes during and after 1957. Of these, about 80 per cent had slip vectors with the

Fig. 4. An orthonormal projection of the North Pacific centred on the Mercator Pole. Slip vectors are tangents to concentric circles about the centre.

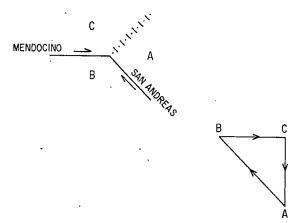

Fig. 5. Both the Mendocino and San Andreas faults can be strike slip if there is a trench to the north or east.

correct sense of motion and within $\pm 20^{\circ}$ of the direction required by Fig. 3. Most of the fault plane solutions for earthquakes before this date also agreed with the sense and direction of motion. Representative slip vectors in Fig. 3 show the motion of the Pacific plate relative to the continental one, which is taken to be fixed. The rotation vector is therefore negative and points inward at 50° N., 85° W. The agreement with theory is remarkable over the entire region. It shows that the paving stone theory is essentially correct and applies to about a quarter of the Earth's surface.

The disadvantage of the Mercator projection is the distortion it introduces around the poles. It is therefore difficult to use Fig. 3 to estimate spreading velocities. For this purpose an orthonormal projection is more useful (Fig. 4), for the spreading rate is then proportional to distance from the centre if this is taken at the pole of rotation. In this projection, which is simply a vertical projection on to a plane at right angles to the rotation axis, rigid rotations of the two plates on a sphere become rigid body rotations on the plane, and all slip vectors must be tangents to concentric circles about the centre of projection (Fig. 4). This projection is useful if spreading rates, rather than angles, are known. There are as yet few such measurements in the North Pacific.

The large active tectonic areas of the North Pacific are now clear from Fig. 3. The fault systems of the San Andreas, Queen Charlotte Islands and Fairweather form a dextral transform fault joining the East Pacific rise to the Aleutian trench. The strike slip nature of these faults is clear from field observations 18-20 and from the fault plane solutions (for example, Fig. 2a). In Alaska the epicentral belt of earthquakes changes direction¹⁰ (Fig. 3) and follows the Aleutian arc. The fault solutions also change from strike slip to overthrust16 (for example, Fig. 2b), and require that the islands and Alaska should override the Pacific on low angle ($\sim 7^{\circ}$) faults. Though the direction of slip remains the same along the entire Aleutian arc, the change in strike changes the fault plane solutions from overthrusting in the east to strike slip in the west (Fig. 2c). A sharp bend occurs between the Aleutians and Kamchatka (Fig. 3). Here the fault plane solutions change back to overthrust (Fig. 2d). motion continues as far as Central Japan, where the active belt divides (Fig. 3) and the present study stops. Thus the North Pacific contains the two types of transform faults which require trenches, and clearly shows the dependence of the fault plane solutions on the trend of the fault concerned.

The variation of trend also controls the distribution of trenches, active andesite volcanoes, intermediate and deep focus earthquakes¹. All these phenomena occur in Mexico, Alaska, the Eastern Aleutians, and from Kamchatka to Japan, but are absent where the faults are of a strike slip transform nature. This correlation is particularly obvious along the Aleutian arc, where all these features become steadily less important as Kamchatka is approached¹o, then suddenly reappear when the trend of the earthquake belt changes. Though it is clear from these remarks that the paving stone theory applies to the North Pacific region as a whole, there are some small areas which at first sight are exceptions.

The most obvious of these is the complicated region of the ocean floor off the coast between northern California and the Canadian border²¹. The difficulties begin where the San Andreas fault turns into the Mendocino fault. Fig. 5 shows that the change in trend of the epicentres is possible only if crust is consumed between C and A (or created in B, which is unlikely). The earthquakes along the coast of Oregon²² and the presence of the volcanoes of the Cascade range, one of which has recently been active and all of which contain andesites, support the idea that crust is destroyed in this area. In the same area two remarkable seismic station corrections which possess a large azimuthal variation²³ also suggest that there is a high velocity region extending deep into the mantle similar to that in the Tonga-Kermadec24 region. These complications disappear when the ridge and trench structures join again and become the Queen Charlotte Islands fault.

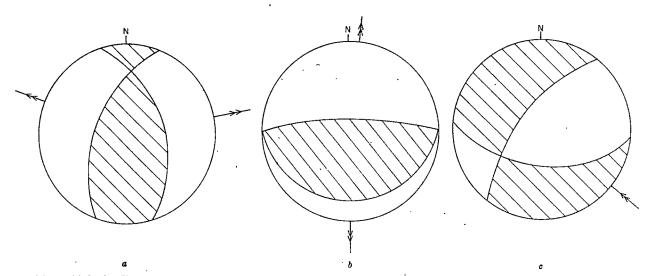

Fig. 6. Mechanism diagrams drawn as in Fig. 2 for three earthquakes in the Kurile Islands. (a) September 15, 1962 (ref. 14), extension by normal faulting. (b) November 15, 1963 (ref. 17), extension by normal faulting. (c) May 22, 1963 (ref. 17), island are overthrust from the Pacific side.

Another complicated area is in Alaska between 147.5° W. and the north end of the Fairweather fault16. In this same area the local uplift after the 1964 earthquake suggested that several faults were active16, and therefore the tectonics cannot be understood without more fault plane solutions.

The third area is in the Kurile Islands where two fault plane solutions (Fig. 6a and b) require dip slip faulting and crustal extension. This motion is completely different from most of the solutions in the area, which agree well with the rest of the North Pacific. Both earthquakes occurred beneath the steep wall of the Kurile trench on the island arc side, and are consistent with gravity slides down into the trench. The terraces which would result from such slides are common features of the trenches of both Japan and the Aleutians^{25,26}. There is also one fault plane solution which requires that the Pacific should be overthrusting the Kurile Islands (Fig. 6c), though the crustal shortening is consistent with the regional pattern.

The two ends of the North Pacific belt may also be discussed with the help of vector circuits. The end in Central Japan gives the trivial result that two trenches can join to give a third. The other end at the entrance to the Gulf of California is the circuit in Fig. 1, and shows how the East Pacific rise and the Middle America trench combine to become the San Andreas transform fault.

The North Pacific shows the remarkable success of the paving stone theory over a quarter of the Earth's surface, and it is therefore expected to apply to the other threequarters. It is, however, only an instantaneous phenomenological theory, and also does not apply to intermediate or deep focus earthquakes. The evolution of the plates as they are created and consumed on their boundaries is not properly understood at present, though it should be possible to use the magnetic anomalies for this purpose. The other problem is the nature of the mechanism driving the spreading. It is difficult to believe that the convection cells which drive the motion are closely related to the boundaries of the plates.

One area where the evolution is apparent lies between the plate containing the Western Atlantic, North and South America¹⁰ and the main Pacific plate. The transform faults in the South-East Pacific are east-west; therefore the ocean floor between the rise and South America is moving almost due east relative to the main Pacific plate. The motion of the Atlantic plate relative to the Pacific is given by the San Andreas, and is towards the south-east. If the motion of the Atlantic plate is less rapid than that of the South-Eastern Pacific north of the Chile ridge, then the crust must be consumed along the Chile trench. The faults involved must have both overthrust and right-handed strike slip components. present motion on the San Andreas is not in conflict with the east-west transform faults of the North-Eastern Pacific if there was originally a plate of ocean floor between North America and the main Pacific plate joined to that which still exists to the west of Chile. This piece of ocean floor has since been consumed, and therefore the direction of spreading in the Pacific appears to have changed in the north but not in the south. This explanation requires changes in the shape of the plates but not in their relative motion, and therefore differs from those previously suggested^{2,6}. This study suggests that a belief in uniformity and the existence of magnetic anomalies will permit at least the younger tectonic events in the Earth's history to be understood in terms of sea floor spreading.

We thank H. W. Menard for his help.

Solar Oblateness and Magnetic Field

by P. A. STURROCK J. J. GILVARRY*

Institute for Plasma Research, Stanford University, Stanford, California

it has been suggested that the observed Solar oblateness may be caused by a gravitational quadrupole moment. The answer may not be so simple, however, because of magnetic stress and differential rotation between the radiation layer and the core.

This article deals with the interpretation of the experiment recently reported by Dicke and Goldenberg1, which shows that certain optical observations of the Sun indicate an oblateness $\Delta=(R_{\rm eq}-R_{\rm pole})/R_{\odot}$ of $(5\pm0.7)\times10^{-5}$, corresponding to $R_{\rm eq}-R_{\rm pole}\approx35$ km. This exceeds by 27 km the oblateness attributable to the mean apparent solar

* Permanent address: Ames Research Center, NASA, Moffett Field, California.

Dicke and Goldenberg suggest that this is evidence for a gravitational quadrupole moment caused by a core flattened by rapid rotation, and that this weakens the agreement between the implications of Einstein's gravitational theory and the otherwise unexplained residual advance of the perihelion of Mercury.

This inference from the observations involves a number of assumptions about processes and conditions in the interior of the Sun. Questions concerning the fluid-dynamical assumptions have been raised recently by Howard, Moore and Spiegel². Our purpose is to assess the role of the Sun's magnetic field—at the photosphere, in the convection zone, in the radiative core and at the interface of these two regions.

The argument of Dicke and Goldenberg rests on the following lemma of the von Zeipel theorem³: If a star is rotating uniformly (with angular velocity Ω), and if all forces other than the pressure gradient are derivable from a potential Φ , then pressure p, density ρ and temperature T have constant values on the equipotential surfaces $\Phi = constant$. If there are no forces other than the pressure gradient and gravity¹, then $\Phi = \varphi - \frac{1}{2}\Omega^2 r^2 \sin^2 \theta$, where φ is the gravitational potential.

Although the phenomenon of solar differential rotation⁴ indicates that there is a force system below the photosphere which is not curl-free, with the consequence that the von Zeipel lemma may not be applied to the interior of the Sun, Dicke and Goldenberg point out that it is sufficient for their purpose that the lemma may be applied, with negligible error, to the "seen layers", that is to the vicinity of the photosphere. Roxburgh⁵ has suggested that the differential Coriolis force associated with differential rotation may invalidate the von Zeipel lemma, but this is open to objection⁶.

Because the Sun's magnetic field represents a force system which is not necessarily curl-free, one may ask whether the photospheric magnetic field can effectively invalidate the von Zeipel lemma. If it cannot, the strong statement of the lemma greatly simplifies the problem¹; if it can, more detailed calculations concerning the photospheric structure are necessary.

If there were no gravitational quadrupole moment, the equipotential surfaces would have a small oblateness, $\delta \approx 10^{-5}$, corresponding to the mean apparent rotation rate. If the most rapid systematic variation of magnetic field is in the radial direction, the component of the force equation in the meridional plane and tangential to the photosphere is

$$-\rho g(\Delta - \delta) \sin 2\theta + \frac{1}{4\pi} B_r \frac{\partial B_{\theta}}{\partial r} = 0$$
 (1)

where the gravitational acceleration (g) is 2.7×10^4 cm sec⁻² and the density of the photosphere at the visible limb of the Sun (ρ) is approximately 2×10^{-8} g cm⁻³. If the magnetic field were randomly oriented, the mean magnetic-stress contribution to equation (1) would be zero. If, however, there were a stress system below the photosphere tending to produce oblateness, this would lead to a systematic distortion of the magnetic field such that the magnetic term of equation (1) would also tend to produce oblateness. If, for the present estimate, the magnetic field is assumed to be almost radial at the photosphere, the magnetic force density can be expressed as

$$\frac{1}{4\pi} B_{r^2} R_{C^{-1}}$$

where R_C is the radius of curvature of the projection of magnetic field lines on to the meridional plane.

The value of 1 gauss is often quoted for the "general" magnetic field of the Sun, based on the work of the Babcocks, but this general field is confined to the polar regions (latitude > 55°). Moreover, as Bumba, and others have emphasized, this value represents a highly integrated measurement, and much greater values are obtained if greater resolution is used. For our purposes, we need an estimate of the root-mean-square magnetic field, in quiet regions of the sunspot zone rather than in the polar regions, derived from measurements made with as fine a resolution as possible. Such measurements have been

made by Howard¹⁰, who finds the root-mean-square value of the photospheric magnetic field to be $8\cdot2\pm4\cdot4$ gauss. It is clear from the work of Severny¹¹ and Sheeley¹² that the polar field also is highly inhomogeneous, so that the root-mean-square value must be substantially greater than the average value. It therefore seems realistic to adopt 8 gauss as the best present estimate of the root-mean-square value of the photospheric magnetic field, but a somewhat smaller value would not change the conclusions which follow.

With the value of the root-mean-square field, the magnetic stress can meet the requirement of equation (1) if the variation of the magnetic field with radius is such that magnetic field lines have a curvature of 2,000 km or Severny¹³ claims, from a comparison of transversefield Zeeman measurements of different spectral lines. that the photospheric magnetic field changes substantially on a radial scale of 100 km. Hence observational evidence, as far as it exists, provides for the possibility that the photospheric magnetic field varies rapidly with depth. If this is so, one must determine the extent to which the visible photosphere can depart from a surface of constant effective gravitational potential by calculations, more detailed than those incorporated in the von Zeipel lemma, based on the force equation and the energy transport equation.

If it is possible that the von Zeipel lemma is not applicable to the solar photosphere, one must examine the possibility that forces other than gravity may be responsible for the observed oblateness, the internal distortion being coupled to the surface distortion by magnetic stresses. It is now possible that the forces responsible for the oblateness are located in the convection zone, a possibility which does not exist if the von Zeipel lemma is applicable to the photosphere. Because a complete theory of the convection zone, which accounts for differential rotation and the solar cycle, has yet to be developed, there is no way of estimating the magnitude and character of the force-field of the convection zone, so that there is no way of determining whether or not these forces lead to photospheric oblateness.

We may now estimate the effect of a "horizontal" magnetic field in the convection zone, such as that envisaged in the Babcock model of the solar cycle¹⁴. The radial component of the force equation may be written as

$$\rho g = -\frac{\mathrm{d}p_G}{\mathrm{d}r} - \frac{\mathrm{d}p_M}{\mathrm{d}r} \tag{2}$$

where p_G and p_M are the gas and magnetic pressures, respectively. Because the magnetic field is "frozen" into the plasma, we should consider a model in which the magnetic pressure increases with gas density. A convenient simple model is to assume that $p_M/p_G=\varepsilon$, where ε is constant throughout the convection zone. Then we see from equation (2) that the scale height H is increased to $(1+\varepsilon)H$ so that the photosphere is raised by a height h given by

$$h \approx \varepsilon D$$
 (3)

where D, the depth of the convection zone¹⁵, is about 10^5 km. To explain the observed oblateness, we need $\epsilon \approx 3 \times 10^{-3}$ which corresponds to a toroidal magnetic field increasing in strength from about 6 gauss at the photosphere through about 2,000 gauss in the centre of the convection zone to about 8×10^5 gauss at the bottom of the zone. Somewhat higher field strengths in the outer layers would obviate the need for very intense fields in the lower layers. The existence of strong magnetic fields in sunspots points to the existence of a magnetic field of some thousands of gauss in the convection zone.

These considerations open the possibility that the observed oblateness may be a consequence of non-

gravitational forces. But even if the oblateness is ascribed to a gravitational quadrupole moment, this does not unambiguously indicate a rapidly spinning core. It is important to note that the core may retain a strong magnetic field, possibly of order 10° gauss, of primaeval origin. If U_M is the magnetic energy of the core and U_{GB} the gravitational binding energy, the departure from sphericity is expected.

$$\Delta \approx 5 \, \frac{U_M}{U_{GB}} \tag{4}$$

For the Sun', $U_{GB} \approx 10^{40}$ erg, from which we find that the observed oblateness might be produced by an internal magnetic field of average strength about 2×10^6 gauss. Thus if the magnetic field of stars is primaeval in origin, and if the original magnetic field of the Sun is now confined primarily to the radiative core, the resulting stresses are likely to produce a deformation of the equipotential surfaces comparable with the photospheric distortion measured by Dicke and Goldenberg.

The recent calculation of Weber and Davis¹⁷ yields 10³¹ dyne cm as an estimate of the torque exerted on the photosphere by the solar wind, through the agency of the magnetic field. This torque is sufficient to halve the angular momentum of the convection zone in a few million years. This implies that the radiative core exerts a torque on the convection zone which is approximately equal and opposite to that of the solar wind on the convection zone. Because part of the torque is caused by viscosity, this imposes an upper limit on the magnetic flux linkage of the radiative core and convection zone.

Using spherical polar co-ordinates, we find that the magnetic torque at the interface of the radiative core and convection zone is approximately $r^3 < B_r B_{\varphi} >$. Hence $\langle B_r B_{\varphi} \rangle$, the average value of $B_r B_{\varphi}$ over this interface, may not exceed 0.05 gauss². Because a velocity shear at the interface will ensure that any magnetic flux crossing the interface will be stretched in such a way that the magnetic stress opposes the velocity difference, we may assume that the magnetic stress had the same sense over the interface. If the three magnetic field components are comparable in magnitude, the average value of the magnetic field must be less than about 0.3 gauss. If the field is normal to the radial vector and of strength 104 gauss, the radial (flux-linking) component must be less than 5×10^{-6} gauss. If it is considered unlikely that the flux linkage between the radiative core and the convection zone is so small, it must be considered unlikely that the angular velocity of the core differs significantly from the mean angular velocity of the photosphere.

In this connexion, we should further note that the solar wind depletes the entire gas-content of the convection zone in about 10° years, so that gas lost from the convection zone at the photosphere is continually being replaced by an outward flow of gas from the radiative core. Such an outward migration of gas must be expected to entail also an outward migration of magnetic field, which adds to the difficulties contingent on the assumption that there is negligible magnetic coupling between the radiative core and the convection zone.

The foregoing considerations imply that the observations of Dicke and Goldenberg may prove more significant in understanding the solar interior than in understanding gravitation. If further analysis of the effects of the solar magnetic field and of solar differential rotation confirms that the photosphere is not necessarily a surface of constant effective gravitational potential, then we must wait for a detailed understanding of all the forces—due to gravity, magnetic fields, differential rotation and convection—before we can interpret the observed oblateness.

If it is determined that factors such as the differential Coriolis force and the photospheric magnetic field do not prevent the photosphere from relaxing to a surface of constant effective gravitational potential, or if the forces in the convection zone produce negligible distortion of the photosphere, then it may be concluded that the observed oblateness provides evidence for a gravitational quadrupole moment. It does not follow, however, that the gravitational quadrupole moment is of such a simple type that it gives rise to a pure oblateness of the photosphere; nor does it follow that the axis of symmetry, if any, of the distortion is coincident with the axis of rotation of the photosphere.

If conclusive arguments can be found which preclude a strong internal magnetic field, or if it can otherwise be decided that the oblateness is caused by a rapidly spinning core, then the gravitational quadrupole moment can be represented by a single second-order spherical harmonic with respect to the axis of rotation of the core. It is possible that detailed understanding of the nature of the internal and external torques exerted on the convection zone will lead to the conclusion that the axes of rotation of the radiative core and of the convection zone differ by only a negligible amount. It will be shown, however, in the subsequent article that a difference of about 3° is crucial in interpreting the residuals of the orbital elements of the planets. Although the data of Dicke and Goldenberg do not readily permit an estimate of the maximum permitted inclination of the rotation axis of the photosphere and the axis of the spheroidal distortion, their graphical results give ±15° as outside limits on the difference in longitudes of the nodes of the equatorial planes of the photosphere and of the spheroidal distortion.

Furthermore, it should be remembered that the angular momentum of the solar system presents anomalies which may be related to the angular momentum of the radiative core. In particular, the rotational axis of the photosphere and the angular momentum vector of the solar system (of which the dominant contribution is caused by the planet Jupiter) have a relative inclination of about 6°. If we admit the possibility that the angular velocity of the radiative core is decoupled from that of the convection zone, it may be that there is a relationship between the angular momentum vector of the core and that of the solar system as a whole, rather than that of the convection zone. If such a discrepancy between the axes of rotation of the radiative core and the convection zone cannot be ruled out on theoretical grounds, it will be necessary to determine by observations of the Dicke-Goldenberg type, or otherwise, the spherical-harmonic coefficient and the three coefficients determining the axis and rotation rate of the core.

If there are no conclusive arguments against the existence of a strong internal magnetic field, it is no longer justifiable to assume that the gravitational quadrupole moment may be represented by a single spherical-harmonic coefficient. In this case, to obtain the information necessary for interpreting planetary orbits, one will need to determine the five second-order spherical-harmonic coefficients with respect to the axis of rotation of the core, plus the three coefficients characterizing the axis and rotation rate of the core.

The observations reported by Dicke and Goldenberg covered a period of four months, but a sequence of observations of the type envisaged in the previous two paragraphs must necessarily extend over quite a long period. In any case, it is clearly desirable that these observations should cover at least one half of a 22 year solar cycle, because variation of the observed oblateness with the solar cycle would indicate that the effect has its origin in the convection zone and therefore has no gravitational significance.

Because the interpretation of the observed photospheric oblateness involves many questions of solar physics which at present seem difficult to answer, one may enquire whether the gravitational quadrupole moment of the Sun may be determined by methods other than

those used by Dicke and Goldenberg. This question is discussed in the following article 18.

Solar Oblateness and the Perihelion Advances of Planets

by J. J. GILVARRY Ames Research Center, NASA, Moffett Field, California

P. A. STURROCK

Institute for Plasma Research, Stanford University, Stanford, California

Observations of the oblateness of the Sun suggest that it may have a rapidly spinning core. An experiment to test this suggestion, by comparing the perihelion advance of a small artificial planet of high eccentricity and Mercury, is discussed.

THE suggestion that the radiative core of the Sun may be rotating much faster than the observed surface may affect the agreement of the observed advance of the perihelion of Mercury with the prediction of general relativity1,2. Furthermore, it has implications with respect to the origin of the solar system, the evolution of stars and the role of stellar winds (in particular the solar wind)1,2. visual observations of the photosphere by Dicke and Goldenberg³ make it possible to infer the existence of such a rapidly spinning core of the Sun only on the basis of the validity of the von Zeipel lemma, implying that the observed surface is one of constant gravitational and centrifugal potential, and that the radiative core does not possess a strong internal magnetic field.

It has been pointed out4, however, that the conditions of the von Zeipel lemma may be violated by virtue of photospheric magnetic fields, in which case non-gravitational forces in the convective zone may induce an oblate-(or possibly prolateness) superimposed on the possible oblateness caused by a gravitational quadrupole moment. The optical oblateness measures the sum of these two effects, but only the latter produces a peri-helion advance of a planet. The purpose of this article is to discuss the implications of the preceding considerations on the test of gravitational theories provided by the excess advances of the perihelia of planets (in this context, excess advance means the difference between the observed advance of the perihelion and that computed on the Newtonian theory with the possible effect of solar oblateness ignored). Furthermore, a dynamical method is suggested of checking the existence of a gravitational quadrupole moment of the Sun which is independent of the inevitable uncertainties inherent in the interpretation of an optical oblateness. Finally, it will be pointed out that the possibility of decoupling of the radiative core and the

convection zone of the Sun, raised by the argument of Dicke and Goldenberg, may significantly affect, by virtue of a small angular deviation in the corresponding axes of rotation, the extent to which the discrepancies in the motions of the major planets from their predicted values can be identified as arising from non-Newtonian effects.

If the previous arguments4 are valid, it is possible that the solar oblateness observed by Dicke and Goldenberg provides information on the structure of the convective zone rather than evidence for a gravitational quadrupole moment. In this case, the gravitational quadrupole moment might be insignificant as regards perihelion advances of planets, and the visual indications of oblateness may not change the observational status of gravitational theories at all. It would seem that this possibility could be confirmed or disproved theoretically only by more complete theoretical and observational knowledge of the visible layers and the interior of the Sun, leading to resolution of the uncertainties raised in the preceding article4. Alternatively, the question could be resolved by the dynamical experiment to be discussed later.

A second possibility is that a rapidly spinning core, decoupled from the convective zone, indeed, produces a gravitational quadrupole moment of the Sun and a corresponding oblateness of the core. Externally, the gravitational potential would then depart from spherical symmetry through an axially symmetric component $J_2P_2(\cos\theta)/r^2$ at the radial distance r, where P_2 is a Legendre polynomial in the colatitude θ measured from the rotational axis of the core, and J_2 is a numerical coefficient. In view, however, of the possibility that the von Zeipel lemma may not be applicable to the photosphere and the necessity of decoupling the radiative core from the convection zone inherent in the thesis of Dicke and Goldenberg, one cannot identify a priori the

direction of the axis of rotation of the core with that of the observed photosphere. Thus two cases arise, because the directions of the two axes may coincide or they may diverge significantly as regards perihelion advances of planets. On the basis of the preceding discussion, the decision between the two cases cannot be made on theoretical grounds, and one must invoke an observational criterion.

The case of coincidence of the two axes in question is the one assumed tacitly by Dicke and Goldenberg, although their optical observations clearly are inadequate to verify the assumption. For this case, let $v_{\rm GQM} = v_{\rm GQM}(a,J_{z,\rm Mer})$ be the excess advance of the perihelion of a planet of mean distance a arising from the effect of solar oblateness when the coefficient J_2 is assigned the value $J_{2,Mer}$, which makes this advance for Mercury equal to the corresponding total excess advance of the perihelion. The value of v_{GOM} depends implicitly on known orbital elements specifying the orientation of the planetary orbit relative to the solar quadrupole moment. Furthermore, let $v_G(a)$ be the excess advance of the perihelion of a planet of mean distance a produced by non-Newtonian gravitational effects when the entire excess advance for the planet is ascribed to this cause. Then the assumption of Dicke and Goldenberg implies that the excess advance v of the perihelion of a planet can be represented by

$$v = \alpha v_G + \beta v_{GQM} \tag{1}$$

for every solar planet, with α and β constants satisfying $\alpha+\beta=1$. The constant α measures the fractional contribution of non-Newtonian gravitation (whether by general relativity or the scalar-tensor5 theory) to the perihelion advance, and β is a constant given by

$$\beta = J_2/J_{2,\text{Mer}} \tag{2}$$

where J_2 measures the actual quadrupole moment. Note that v_G on the basis of general relativity and v_{GOM} vary inversely with a as the 5/2 and 7/2 power, respectively.

The dynamical test for solar oblateness permitted by equation (1) is possible only if excess advances of the perihelion are known observationally with sufficient accuracy for two or more planets, say, Mercury and either Venus or the Earth. For the latter two planets, however, the accuracies in the determinations of v are inadequate for this purpose, a circumstance arising in the first instance because of the relatively small advances of perihelion. More importantly, the recent determination of the astronomical unit and the mass of the Earth-Moon system by means of radar echoes from Venus has revealed the existence of systematic errors introduced into conventional orbit determinations by inaccuracy in the previously inferred values of these parameters (determined from perturbations of the orbit of the asteroid Eros at close approaches to the Earth)6,7. Concomitantly, actual errors exceeding the quoted probable error by a factor of three are not uncommon in orbital calculations based on optical observations, and greater factors are possibles. Radar observations of the planets, in progress at Lincoln Laboratory, promise an ultimate accuracy in orbit determinations exceeding the present by at least two or three orders of magnitude (private communication from I. I. Shapiro). The question of the actual accuracy of the figure $43 \cdot 1 \pm 0 \cdot 4$ sec/century for the perihelion advance of Mercury must thus await results from the radar measurements.

Because the accuracies in the determinations of the perihelion advances of Venus and the Earth are inadequate for the purpose, the only natural planet that could be conjoined with Mercury for a test of equation (1) is the asteroid (1566) Icarus⁹. For this minor planet, the advance of the perihelion predicted by general relativity is 10·1 sec per century if the corresponding advance of Mercury arose solely from this cause⁸. The conclusions

of Dicke and Goldenberg imply $\alpha = 0.92$ and $\beta = 0.08$, and thus equation (1) predicts v=10.6 sec per century for Icarus on the basis of the results of these authors. No observational determination of v for Icarus exists, and many years of further observations might be required to obtain it. In view of the high figure of merit¹⁰ for precision in fixing the perihelion advance of Icarus, a probable error in a future determination equal to the low value 0.4 sec per century for Mercury might be achieved, but even then the advance implied by the considerations of Dicke and Goldenberg would exceed that predicted on general relativity by only one probable error. Assuming the possibility of an actual error exceeding the quoted probable error by a factor of three in orbital calculations based on optical observations8, one estimates that a definitive result in favour of solar oblateness could be obtained only for $\beta \gtrsim 0.25$. Thus if the value of Dicke and Goldenberg for β is correct, verifying by means of equation (1) from natural planets does not seem possible in view of present inaccuracies in orbit determinations, and the only recourse would seem to be use of artificial planets of high eccentricity and small mean distance11.

If the axes of rotation of core and photosphere do not coincide, use of artificial planets to infer the solar quadrupole moment dynamically becomes necessary a fortiori, because the analogue of equation (1) then involves at least four constants (an additional two are required to specify the orientation of the axis of the solar core with respect to the ecliptic).

The case of different axes of rotation of the solar core and photosphere has a special importance because, long before the work of Dicke and Goldenberg on the visual oblateness, effects which would arise from the lack of coplanarity of the Sun's equatorial plane and the orbital plane of Mercury were cited as militating against the suggestion that solar oblateness produces the excess advance of the perihelion of Mercury¹². The inclinations of the equatorial plane of the Sun's photosphere and the orbital plane of Mercury are nearly the same (7° and 7° 0', respectively)13, and the angle between the corresponding normals has the low value 3° 22'. This small angle, however, corresponds to a significant difference in the longitudes of the ascending nodes, corresponding to 47° 56′ for the Sun and 75° 18′ for Mercury¹³. As a consequence, the rate of decrease of the inclination of Mercury's orbit would amount to -2.3 sec/century if the entire excess advance of the perihelion of Mercury were ascribed to an oblate solar core with equatorial plane corresponding to the photosphere8. Such a large variation of this orbital element is not admissible, because the residual (observed less computed Newtonian value) is only -0.12 ± 0.16 sec/century⁸. Dicke and Goldenberg infer a solar oblateness less by a factor of about ten, and thus allowable in view of the probable error in the residual.

Because, however, the small angular departure in question between the axis of the solar quadrupole moment and the normal to the orbital plane of Mercury is essentially a matter of presumption from the orientation of the equatorial plane of the photosphere4, one can examine the important possibility where it in fact vanishes. In this case, the equatorial plane of the spinning core coincides with the orbital plane of Mercury, and the perturbing force on the planet depends only on the radial distance r(as is strictly true in general relativity). Thus the perturbation affects neither the inclination nor the longitude of the node of Mercury's orbit. Furthermore, no substantive discord appears between observed and calculated variations in orbital elements for any planet, even if the entire excess advance of the perihelion of Mercury is ascribed to the effect of solar oblateness in this case. Under this assumption, results from equations of Shapiro⁸ are shown in Table 1 for the secular rates of change of the argument of perihelion, the longitude of the ascending node and the inclination of the orbits of Mercury and Venus: corresponding values from general relativity

and residuals are shown for comparison. The agreement with the residual in the motions of both the perihelion and the node for Venus is improved and the motion of the former is now direct as implied by the residual rather than retrograde, in contrast to the corresponding case in which the axis of the solar quadrupole moment is taken normal to the equatorial plane of the photosphere. Every predicted variation in orbital elements (including those for the Earth) falls within a limit of two probable errors from the corresponding residual, a bound which is quite acceptable for those observations⁶⁻⁸.

Table 1. VARIATIONS IN ORBITAL ELEMENTS FOR MERCURY AND VENUS PRODUCED BY A GRAVITATIONAL QUADRUPOLE MOMENT (GQM) OF THE SUN WITH AXIS NORMAL TO MERCURY'S ORBIT AND VALUE NECESSARY TO YIELD THE ENTIRE EXCESS ADVANCE OF MERCURY'S PERHFELION, AS COMPARED WITH RESULTS FROM GENERAL RELATIVITY (GR)

Variation		Me	rcury	Venus

^{*} In sec/century.
† This work.
† See ref. 8.

The figures for Venus in Table 1 take into account the direction of the normal to the orbit relative to the assumed axis of the solar quadrupole moment. If the small angular difference involved is ignored, the value of Table 1 for the perihelion advance of Venus is grossly overestimated as 4.9 sec/century14. Thus the variation of the perihelion (and also the inclination) of a planet is quite sensitive to the orientation of the gravitational quadrupole moment. The physical reason is that the argument of perihelion is measured from the line of nodes, fixed by an angle of intersection of two planes which is usually small, so that the relevant equations correspond almost to a singular case. This strong sensitivity does not appear in the longitude of perihelion, which is measured from the vernal equinox.

The implication of Table 1 is that any fraction from zero to unity of the excess advance of Mercury's perihelion can be explained by a gravitational quadrupole moment arising from a spinning solar core with axis aligned sufficiently close to the normal to Mercury's orbit, with an observational disagreement in the variation of orbital elements for any planet. Consistency with the result of Dicke and Goldenberg for the visual oblateness, however, requires either that the fraction be small (of the order of 10 per cent) or that the deformation induced in the photosphere by the rotating core be partially compensated by a negative contribution from forces in the convection zone. It must be understood that we are not proposing that the excess perihelion advance of Mercury is indeed caused purely by a gravitational quadrupole moment; our purpose is, rather, to emphasize that the range of possibilities is markedly extended once one relaxes the assumption that the axis of the gravitational quadrupole moment coincides with the rotational axis of the Sun's photosphere.

As a final possibility, it can be mentioned that significant contributions to the excess advances of the perihelia of planets may be produced by a gravitational quadrupole moment arising from distortion of the solar core by a strong magnetic field rather than by rapid spin. In this case, there is no reason to believe that the departure of the gravitational field from spherical symmetry can be represented adequately by only one spherical harmonic of second order, and the data of Dicke and Goldenberg are insufficient to justify such an assumption. Thus the term corresponding to the effect of solar oblateness in the analogue of equation (1) must depend on eight independent parameters, for a total of nine which must be fixed by observation of planetary orbits.

These considerations by no means rule out the possibility of a significant contribution from solar oblateness to the

advance of the perihelion of Mercury. In fact, it has been shown that, at the present stage of knowledge, the observational data admit the possibility (dependent on the orientation of the quadrupole moment) of a contribution from solar oblateness significantly exceeding the value inferred by Dicke and Goldenberg. It would seem that a conclusive test separating the relativistic effect from that of solar oblateness could only be achieved by combining data from the orbit of Mercury with those of artificial planets launched into highly elliptical orbits of mean distance approaching one-half that of the Earth. In this case, the maximum value of the perihelion advance possible for an orbit grazing the Sun becomes 11.6 sec, yr on the basis of general relativity, larger than the value for Mercury by nearly two orders of magnitude. The relatively large value of the excess perihelion advance possible in these conditions, coupled with highly precise radar observations of position and velocity by means of transponders, should permit dynamical evaluation of the solar oblateness within a decade at the most, if a determined effort were made with the resources of modern space technology.

For such orbits permitting close approach to the Sun. many perturbations which ordinarily are negligible would have to be considered and determined in order to exploit the full potentiality of the proposed method. Thus the effects of sunlight pressure and of solar corpuscular radiation, and charge and neutral drag in the extended solar corona, would have to be evaluated15. The reflexion properties and possibly the orientation of the artificial planet, dependent on its characteristics, may have to be known quite accurately in order to compute with sufficient precision the perturbation caused by sunlight pressure.8. Finally, the necessity of cancelling the orbital velocity of the Earth for nearly direct fall of the body into the Sun raises some problems of size for the booster rocket.

In brief, it may be concluded that improved understanding of gravitation may spring either from advances in solar physics or from advances in space science. If this knowledge arises from space science, it may come from the experiment proposed here, from studies of relativistic effects in radar observations of the orbits of Venus and Mercury, as suggested by Shapiro¹⁷, or from analysis of the precession of a gyroscope in a satellite orbiting around the Earth, as proposed by Schiff18 and by Everitt and Fairbank¹⁹.

Solar Oblateness

by

I. W. ROXBURGH

Department of Mathematics, Queen Mary College, University of London In this article the author answers criticism, by Dic Goldenberg, on his theory of why the Sun is oblate.

RECENTLY, in an article on the oblateness of the Sun¹, I suggested that the observed difference of 35 km between the polar and equatorial radii² could be caused by the effect of uniform rotation on the solar convective zone. Dicke and Goldenberg, in a reply³ refuting this suggestion, did not consider my principal hypothesis, but concentrated only on the weaker peripheral deductions.

My basic suggestion was that the solar rotation interacts strongly with the turbulent convection in such a way that a steeper temperature gradient is necessary in the polar direction than in the equatorial. If the temperature at the base of the convective zone is approximately the same at pole and equator, then the temperature falls to the surface value in a shorter distance in the polar direction than in the equatorial. Thus the surface is oblate.

In support of this hypothesis the following results can be quoted. (1) Investigations of the onset of instability4 do show that rotation inhibits convection when rotation and gravity are parallel (the polar case), but not when they are perpendicular. (2) Investigations by Weiss⁵ and myself on turbulent convection in a rotating system give the suggested result, although the magnitude of the effect cannot be accurately predicted because there is no satisfactory theory of turbulent convection. (3) Although rotation can only have a small effect in stable zones, because the ratio of centrifugal force to gravity is small, this need not be the case in turbulent convective zones. In some respects gravity is weakened by a factor of the ratio of the superadiabatic temperature gradient to the actual temperature gradient (which is small compared with unity), so that even a slow rotation could conceivably have a large effect.

Certain deductions can be made from the hypothesis which supports the general idea. In particular, the different temperature gradients in the polar and equatorial directions imply a temperature and thus a pressure difference over a surface of constant density. The resulting latitudinal pressure force has to be balanced by motions other than uniform rotation, and the observed equatorial acceleration of the Sun could be taken as evidence of such an effect. Dicke and Goldenberg consider that their model with a rapidly rotating core provides several mechanisms to explain and maintain the equatorial accelerations while the model I proposed does not. In my original paper I considered a radial angular velocity This need not necessarily be the case; the actual variation would depend on the latitude dependence of the excess pressure over an equidensity surface which could only be obtained by a more detailed analysis. As far as the maintenance is concerned, Kippenhahn⁶ and co-workers have found that a circulation in the convective zone (in this case driven by the pressure excess) is

capable of maintaining equatorial acceleration in a envelope.

Dicke and Goldenberg list three of my origin.

for answer. (a) The surface of the Sun is located where
the temperature equals the effective temperature; (b) if
the solar core were rapidly spinning, the polar flux would
exceed by about 1 per cent that at the equator; and (c)
the excess oblateness of 27 km is caused by an internal
temperature gradient and a large positive radial gradient
in angular velocity.

I agree with their statement that the $T=T_{\rm eff}$ is not the observed solar limb, which is at an optical depth of about 0·004. This does not affect my conclusion because wherever the limb is situated the temperature is negligibly small compared with the temperature at base of the convective zone, and can be taken as zero as far as calculating the oblateness is concerned. Admittedly there is much to be done before we understand the structure of the solar atmosphere, and the exact nature of the adjustment of the atmosphere to the oblate convective zones requires detailed examination.

I agree with Dicke and Goldenberg's doubts over the use of von Zeipel's theorem; however, it is more likely to be valid for the interior than for the surface layers.

I do not state that the oblateness is caused by a radial angular velocity gradient. The oblateness is supposed to be caused by the interaction of rotation and convection. This in turn requires some motion other than rotation. Whether this excess motion is differential rotation in a radial sense or an angular sense, or primarily a circulation, has yet to be resolved.

Finally, one should point out that Goldreich and Schubert (work to be published) have recently found that the Rayleigh-Taylor instability occurs in a stably stratified star, and that therefore the angular velocity must be independent of distance from the equatorial plane and that the angular momentum per unit mass must increase away from the rotation axis. This prevents the development of radial variation in angular velocity and ties the rotation of the solar core to that of the envelope. It is therefore difficult to see how the inside of the Sun could be rotating faster than the outside as required in the Dicke model.

Generation of Radio Sources

by
G. BURBIDGE
Department of Physics,
University of California, San Diego,
and
Institute of Theoretical Astronomy,
University of Cambridge

Many radio sources have a double character, and high resolution studies show small components. It is suggested that radio sources may be made up of many small sources.

THE discoveries of the past few years have shown that extragalactic radio sources originate either in galaxies of various kinds or in the quasi-stellar objects. The possibility that there is yet another class of source is not excluded. The bulk of the radiation is emitted by the synchrotron process, and it was shown more than a decade ago that the great distances of the radio sources and their large sizes necessarily imply that a tremendous amount of energy must instantaneously be present in the form of magnetic flux and relativistic particles in such sources. Accurate estimates of the total energy present are not possible because no independent method of measuring the mean magnetic field in the radio sources has yet been found. Thus the most conservative estimates have been made, and these are obtained when there is approximate equipartition between magnetic and particle

energy, $E_p = \frac{4}{3} E_m$. The minimum total energy is then $E = \frac{7}{3} E_m$.

The very large energies which must be released in the radio sources have been a subject of intense investigation, and in nearly all theories it is now argued that this energy is largely gravitational in origin. The mechanism by which this energy is transferred into relativistic particles, however, still remains obscure. Little attention has so far been paid in the literature to the problem of understanding the shapes or brightness distributions of the synchrotron sources. It is this problem that I wish to examine in this article.

There are two major features which need to be explained. The first is the well known double character of the radio sources. The second is the fact that, in a considerable proportion of sources, high resolution studies are now showing that very small components with high surface brightnesses are present. The very small radio components are frequently found in the nuclei of the galaxies with which the radio sources are identified, or are coincident with the optical quasi-stellar objects. Well known examples are 3C 84, various core-halo objects, the small diameter sources investigated by long baseline interferometry or by scintillation techniques, and all the objects which are found to vary. There are a number of cases, however, where there is evidence for small configurations of high brightness far from the nuclear regions of a galaxy. Examples are the structure of Cygnus A recently described by Wade¹, the small high-surface-brightness regions recently discovered in M 87 which may lie along the optical jet (private communication from D. Hogg) and the remarkable double sources 3C 33 (ref. 2), 3C 343 and 343·1 (refs. 3 and 4), and PKS 0453-30, 0456-30 (ref. 5), which have very small sizes when compared with their separations. There are also objects such as 3C 225 and 30 267 (ref. 6) each of which contain a highly compact source. They are both double sources of unequal intensity. In both cases the compact source is of very small angular diameter $\gtrsim 0.2^{\prime\prime}$

Also of great interest are very small sources such as

CTA 21 and 3C 49 (ref. 7) which seem to lie in empty fields. They may be centred on massive objects which are emitting at optical frequencies at very low levels. Alternatively, they may be small sources which have been ejected from a distant galaxy or quasi-stellar object.

It is by now well established that the radio sources are generated by violent outbursts in the nuclei of galaxies or other massive objects. Thus the occurrence of a very small central component associated with an optical object suggests that this is the seat of the outburst which is still taking place. The double nature of the sources and particularly the existence of very small intense sources far from the seat of the explosion, however, have not been satisfactorily explained. It has been generally argued that relativistic particles are ejected freely from the nucleus. because it is clear that if a cloud expanded adiabatically the initial energy would be unreasonably high. To obtain a double source it has been argued that the presence of interstellar matter and magnetic field in a disk-like distribution will lead to ejection normal to the disko, or ejection controlled by the magnetic field configuration of the galaxy¹⁰. Once the particles have escaped from the main confines of the galaxy, however, there is little to confine them, and the problem of the persistence of two discrete components is a severe one.

It has been argued that the particles are effectively moving freely⁶, their trajectories being determined by their passage through the galaxy, that they are moving in a region of enhanced magnetic field and that the time scale of the radio source is determined by the time taken to traverse this region (about 10⁶ years). Such a scheme, however, will not explain the presence of small discrete sources very distant from the explosion centre. Some mechanism of confinement outside the galaxy is required. Gold¹⁶ has therefore suggested that this confinement is caused by the presence of a comparatively strong (about 10⁻⁶ gauss) intergalactic magnetic field. This field must have a cosmological origin. Gold has attempted to show that such a field would exert sufficient pressure on the boundaries of a source such as Cygnus A treated as a simple double, so that it could be confined.

The volume of the Cygnus A source is estimated to be 1069 cm3, while its minimum total energy content is about 3×10^{60} ergs (ref. 11). Here it is assumed that the proton energy is 100 times the electron energy. If the electrons alone are present the minimum total energy is about 1059 ergs. Thus the mean energy density in the source is about 3×10^{-9} to 10^{-10} erg/cm³, the pressure exerted is about 10^{-9} to 3×10^{-11} dynes/cm², and the minimum magnetic field necessary to equalize the pressure inside and outside the source must lie in the range 10-4 to 10-5 gauss. These values are higher than those given by Gold because he assumed a total energy content of about 1058 ergs which is considerably below the minimum total energy which must be instantaneously present to explain the radio source on the synchrotron theory if a single coherent source is involved. Such magnetic fields are unreasonably large. In widely spaced doubles like 3C 33 and PKS 0453-30, 0456-30, the external magnetic fields

to give significant external pressures need to be about 10^{-5} gauss (these estimates are based on the source identifications and thus distances suggested by Moffet² and by Gardner and Bolton³, respectively). For sources which are smaller than these the total energy densities might be higher, because the energy densities of magnetic flux and relativistic particles are proportional to $L^{4/7}r^{-12/7}$, where L is the total power emitted by the source and r is its dimension. Thus it seems that this mechanism of containing radio sources is not likely to be effective.

Another difficulty with the idea that such sources are contained by an external magnetic pressure is the fact that instabilities that give rise to large-scale loss of particles easily develop in the boundary regions. It has been argued that in a rather similar situation cosmic ray particles which attempt to escape from our Galaxy give rise to instabilities which twist together the magnetic lines of force, thus effectively leading to containment¹². As Cowling¹³ has pointed out, however, thermonuclear experiments lead us to believe that magnetic confinement of this type is exceedingly difficult to attain.

Small Source Model

It can be concluded that the radio sources cannot be controlled by outside forces when they appear outside galaxies, and we are then forced to the conclusion that the small sources must be generated and contained by internal forces. What are the requirements of such a model? We first consider the energetics of sources as a function of their linear dimensions. In the calculations that have been made previously14, it has been supposed that the sources are large clouds containing a homogeneous magnetic field. As soon as we admit the existence of small intense sources, however, it is natural to consider a general model in which it is supposed that the flux is emitted from n similar very small intense sources with dimension r and magnetic field H, rather than from a single homogeneous source of dimension R and magnetic field H_0 . If we wish to adhere to the idea that the equipartition condition prevails so that the total energy in particles and field is a minimum, then it is easy to show that

$$\frac{H}{H_0} = \left(\frac{R}{r}\right)^{6/7} n^{-2} \, {}^{7} \tag{1}$$

Also in equipartition conditions, the ratio of the total energy, $E_0 = (E_p + E_m)$, present in the single large homogeneous source to that in a source made up of n small sources each with energy E is

with energy E is
$$\frac{E_0}{nE} = \left(\frac{H_0}{H}\right)^{-3/2} = \left(\frac{R}{r}\right)^{9/7} n^{-3/7} \tag{2}$$

Let us now consider some possible cases. For an object like Cygnus A, in which fine structure has been detected, we might suppose, for example, $n \simeq 10^3$ and $\frac{R}{r} \simeq 10^3$.

Then $H = 51.8 H_0$ and $E_0 = 373 nE$.

Because the equipartition magnetic field for the homogeneous case has been calculated to be about 2×10^{-4} gauss by Maltby et al.¹¹ we see that for this example the equipartition fields in the sub-sources are about 10^{-2} gauss and the total energy necessary to give rise to the source is reduced to about 10^{58} ergs. At the same time the lifetime of the source, calculated by dividing its total electron energy content by the power radiated, is also reduced by the factor (E_0/nE) .

In a large source in which no fine structure can be detected we might argue that there are a very large number of very small sub-sources. For example, we might consider $n = 10^5$, $R/r \approx 10^5$. Then $H/H_0 = 720$ and $E_0/nE = 1930$

If single very small sources are ejected and are found to be comparable in intensity with single large sources, then we have simply that

$$\frac{H}{H_0} = \left(\frac{R}{r}\right)^{6/7} \text{ and } \frac{E_0}{E} = \left(\frac{\dot{R}}{r}\right)^{9/7}.$$

Thus for

$$\frac{R}{r} = 10^6, \frac{H}{H_0} = 1,930, \frac{E_0}{E} = 2.7 \times 10^{6}$$

These examples show that if the radio sources are made up of numbers of small objects, the magnetic fields in them are likely to be much stronger than those usually assumed, the instantaneous energy requirements are much lower, and also the time scales are correspondingly shorter.

In all the calculations that have been made either assuming large homogeneous regions or in models of this type, it has been assumed that the equipartition condition prevails. No physical reason for the development of such a situation, however, has been given and it has been pointed out that even in the case of large homogeneous sources departures from this condition are probable. If a radio source is made up of small coherent sub-regions, there is no reason to believe that equipartition between particles and field develops here, and we can only take the values given here as possible indicators of what the true parameters are. The small objects must be comparatively stable during the period in which they are ejected from the nuclear region of the galaxy or quasi-stellar object.

What are the requirements of such sub-sources? A simple model of such an object might consist of a highly condensed object of mass M, surrounded by a gas cloud of density ρ containing the magnetic field of strength H. The kinetic or turbulent velocity in the gas is v. If the magnetic field is to be controlled gravitationally we must have that

$$\frac{GM}{r'} \gtrsim \frac{H^2}{8\pi} + \frac{1}{3} \rho v^2$$

where r' is the size of the region of magnetic field and gas which is controlled by the central condensed object. (r' is not necessarily the same dimension as r described earlier). We have also assumed that the relativistic particle pressure is small compared with the magnetic pressure so that it has been neglected. Now, for example, if we put v=1,000 km/sec, and $H=10^{-2}$ gauss, then provided that $\rho < 10^{-21}$ g/cm³, the second term on the right-hand side can be neglected and we find that

$$\frac{M}{\tilde{r}'} \gtrsim 6 \times 10^{22}$$

If we suppose that equilibrium is maintained, then for values of r' ranging from 10^{-2} to 1 parsec, $M \sim 10^{6}$ to 10^{8} M $_{\odot}$. At first sight it seems that, if the magnetic field and gas density are lower than the values just assumed, M/r' is reduced. Proper account, however, should be taken of the effect of the relativistic particles. The pressure exerted by these particles may well dominate, because if we assume weaker fields their energies must be correspondingly higher according to the synchrotron theory.

This may very well mean that the small massive objects are simply the centres which are able continuously to maintain the radio source by the ejection of relativistic plasma and magnetic flux and that there is no gravitational stability.

Thus the small source structure far from the explosion centre may not be due to containment by the small massive objects which have been ejected, but to continuous injection from them into the surrounding region.

The mechanism of ejection of such objects is not understood, but we might assume (1) that they are ejected with velocities in excess of the velocity of escape from the parent galaxy or massive object, so that perhaps $v_e > 1,000 \text{ km/sec}$ and (2) that the velocities are not highly relativistic so that v < 0.1 c. With these assumptions, the time scales associated with the ejection lie in the range 10^8 to 3×10^8 years, and the kinetic energy involved is 10^{56} n to 10^{60} n ergs. Because n may range all the way from unity to about 10^5 it is clear that the major part of the energy of the fragments ejected in the explosion, and not the energy instantaneously present in particles and field arising from the fragments.

The dynamic lifetimes estimated here may be short compared with the lifetimes recently estimated by Schmidt¹⁵ from frequency arguments, which range as high as 10° years. It is obvious that lifetimes as long as this require repeated ejection of fragments. If the total number of fragments ejected over the whole lifetime of the source is n, and we consider a strong source ($L \simeq 10^{44}$ erg/sec) which lasts for 10° years, then the mass energy released per fragment, perhaps involving many generations of relativistic particles, is $3 \times 10^{39} \ n^{-1}$ g. For values of n ranging between 1 and 10^5 , we see that the mass converted may be only a small fraction of the total mass of a fragment.

Conclusions

We have briefly explored the small source model because it seems that this kind of model is the only one capable of explaining the existence of small sources of high surface brightness which are found far from the explosion centre, both in larger sources and by themselves. The idea that large sources are made up of many small ones then follows naturally, though it might be possible to show that comparatively small fluctuations in surface brightness might be produced in a large source by instabilities.

If radio sources are generated by the ejection of small massive objects thrown out from the central outburst, severe restrictions are placed on the class of model which is invoked to release energy. None of the proposals that have been made, in which it is argued that particles are ejected or accelerated as a free gas—as is the case in supernova or star collision theories, or in flare mechanisms is satisfactory. We must go back to the models having single massive objects in gravitational collapse¹⁶. It must then be argued that it is the splitting or fragmentation of such an object which gives rise to the energy in the form of smaller massive objects. The double nature of the source must be traced to the distribution of momentum in the initial fission or fragmentation. The fragments which are ejected are then able themselves to eject relativistic particles directly. Such fragments can be likened to miniature quasi-stellar objects, and some of them may have been ejected from such objects.

The overall energetics in such a model may be similar to those invoked in the earlier investigations and it is clear that the initial outburst must involve a very massive object (1010 Mo or more in most cases). however, of no way to make good estimates of the energies of the particles or the strengths of the magnetic fields, or the masses of the material ejected directly from the observations. Thus the figures which have been used only give a very rough indication of these parameters.

We have not discussed the polarization of the radio sources in this preliminary investigation. In some sources,

such as Centaurus A (NGC 5128), Fornax A (NGC 1316) and MSH 13-33 (IC 4296), a fairly high degree of polarization or a regular pattern is seen¹⁷. In very small condensed sources a significant degree of polarization might be expected. If, however, a large source is made up simply of a considerable number of small sources there is no obvious way in which a large net polarization could be obtained, unless the magnetic field between the objects has a regular structure. This might require that there is some gas between the small sources. The most probable source of such gas and magnetic flux is the explosion itself. because there is at present no evidence for any intergalactic matter or magnetic field.

I thank the Master and Fellows of Churchill College for hospitality during the summer of 1967. This work was supported in part by the US National Science Foundation and in part by NASA.

Note added in proof. Since this paper was submitted for publication, DeYoung and Axford (Nature, 216, 129; 1967) have described a model in which they argue that radio sources may be confined by a dynamical process where the internal pressure of the source is balanced by the ram pressure of the intergalactic gas. If there is enough intergalactic gas, and there is no evidence for this at present, a modest degree of confinement may be achieved by this mechanism. The existence, however, of sources in which the ratio of separation to size is exceedingly large (~ 102-104) leads me to the conclusion that small massive objects stabilized by their own gravitation must be responsible in these cases. It is then not unreasonable to suppose that the major energy sources are, in general, small objects ejected in the explosion.

Radio Galaxies as Cosmological Probes

by

M. ROWAN-ROBINSON

Department of Mathematics, Queen Mary College, University of London

Applying the luminosity-volume test to radio galaxies, it is found that for the data to fit the usual relativistic cosmological models there must be strong evolutionary factors affecting the distribution of the radio galaxies. The steady state model is inconsistent with the present data.

This article reports the results of applying a new cosmological test to the radio galaxies: the distribution of radio galaxies in space is strongly affected by evolutionary factors. In particular, the steady state model, in which evolution is not permitted, does not seem to be consistent with the present data for radio galaxies. This confirms the conclusion of Rees and Sciama¹ based on the data for quasars, although some authors2-4 continue to cast

doubt on the cosmological interpretation of the red-shifts of quasars. The classical cosmological tests, the magnitude-red-shift and the number-count tests, are of value only in situations where the dispersion in luminosity of the sources is small. This condition does not hold for the radio luminosities of radio galaxies, or for either the optical or radio luminosities of quasars (assuming their red-shifts to be cosmological). The additional factor of completeness down to some limiting flux level, however, enables a far more powerful test, the luminosity-volume test, to be applied

În earlier communications^{5,6} I have described the application of this test to the quasars, and the determination of various possible forms of evolution which give consistency with the usual relativistic cosmological models. When the cosmological term is included in Einstein's equations, these models can be characterized by two parameters⁷

$$\sigma_0 = 4\pi G \rho_0 / H_0^2 \quad q_0 = -(R\ddot{R}/\dot{R}^2)_0$$

where ρ is the smoothed out cosmological density, H = R/R, R(t) is the scale factor of the expanding universe and the subscript zero refers to the present epoch. I have examined models with $0 \le \sigma_0 \le 3$, $-1 \le q_0 \le 3$, and found that for consistency with any of these models some evolutionary factor must be assumed to be affecting the quasars. For example, the fraction of matter in the form of active quasars might have been greater at earlier epochs, or the typical luminosities of quasars at earlier epochs might have been greater.

Luminosity-volume Test

The principle of the luminosity-volume test is that if the distribution of luminosities of a set of sources is independent of epoch, then in any range of luminosity we expect to find equal numbers of sources in equivalent volumes of space. In ref. 5, the radio luminosity-volume diagram was used to demonstrate that for quasars, "density" evolution (the co-ordinate number-density increases with red-shift, but the relative distribution of luminosities is independent of epoch) is at least as consistent with the present observations as "luminosity" evolution (the co-ordinate number-density is independent of epoch, but the typical luminosity increases with redshift). When proper account is taken of the effects of optical selection, and the optical luminosity-volume diagram is also considered, it is found that only for comparatively empty models ($\sigma_0 \ll 1$) are the quasars consistent with luminosity evolution.

Application to Radio Galaxies

The optical luminosities of radio galaxies show small dispersion, so the effect of the limiting visual magnitude of about 20 is simply to confine our identifications to redshifts smaller than 0.4–0.5. Moreover, we can obtain from the observed visual magnitude of a galaxy a rough estimate of its red-shift in those cases where the red-shift has not yet been determined. At present red-shifts are available in the literature of fifty-nine of the one hundred and forty-seven galaxies identified with radio sources in the ravised 3C catalogue of those identified to date with $V \leq 15$ magnitudes, but only 20 per cent of those identified with $15 < V \leq 20$.

Fig. 1 shows the distribution of red-shift of these galaxies against visual magnitude, as estimated by Wyndham¹⁵: six galaxies with red-shifts less than 0·01 (3C 71, 231, 270, 272·1, 274, 386) are omitted. In what follows I shall confine my attention to "strong radio galaxies", that is, those with luminosity greater than 10²³ W ster⁻¹ (c/s)⁻¹, so that of these six nearby radio galaxies, only 3C 274 will concern us.

Sources of the same luminosity and spectral shape would satisfy a relation of the form

$$V = A + 5 \cdot \log_{10} z + K(z) + 5 \cdot \log_{10} \{D(z)/z\} \dots$$
 (1)

where z is the red-shift, K(z) is the K-correction¹⁶ and D(z) is the "luminosity distance"¹⁷.

For small z, equation (1) can be approximated by

$$V = A + 5 \log_{10} z + B z \dots$$
 (2)

where A and B are constants¹⁶. The locus of this form with A=20.5, B=5, is shown in Fig. 1; this is the best line of form (2) through the data, from a least squares analysis.

The scatter of the points in Fig. 1 is primarily caused by the approximate nature of the magnitude estimates, which are probably not more accurate than ±1^m. Other factors are the dispersion in intrinsic luminosity of the galaxies, the effect of galactic obscuration and differences in spectral shape for different types of galaxy. Corrections could be applied for the latter two effects, but the approximate nature of the data hardly makes this worthwhile at the present. It will be seen that errors of up to a magnitude do not alter the basic conclusions.

Naturally, I shall not attempt to determine cosmological parameters from equation (2), because there is the possibility of systematic error in the magnitude estimates, quite apart from the random errors already mentioned. In what follows we assume only that equation (2), with A=20.5 and B=5, is valid to within a magnitude for the uncorrected visual magnitudes of radio galaxies. For the eighty-eight galaxies identified with 3CR radio sources for which no red-shifts are available, we estimate the redshift from equation (2) with A = 20.5, B = 5. For a total of 142 strong radio galaxies we then investigate the distribution of intrinsic radio luminosity against volume, in various cosmological models: we wish to test whether, in any given range of radio luminosity, equal numbers of sources are found in equivalent volumes of space. The total volume of space in which sources of a given luminosity are visible is limited by (i) the limiting radio flux-level of the 3CR catalogue and (ii) for sources of sufficiently high radio luminosity, a more severe limitation arises from the limiting optical magnitude of about 20 magnitudes, which we assume to be equivalent to the restriction $z \le 0.5$. For each range of radio-luminosity considered, the observable volume of space is divided into two. The numbers found are tabulated in Table 1. The columns labelled (a) refer to the nearer half of the observable volume, and (b) the farther.

Because the properties of the relativistic cosmological models do not differ much out to the red-shifts at which

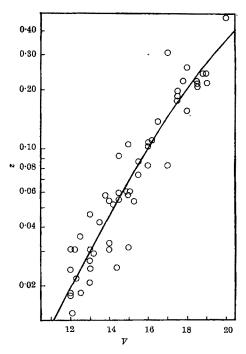

Fig. 1. Red-shift, z, against estimated visual magnitude, V, for fifty-four strong radio galaxies. Solid line: the locus $V = A + 5 \log_{10} z + Bz$, with A = 20.5, B = 5. The majority of the points are within one magnitude of this mean locus.

$\log_{10}\tilde{P} > 24.9$	37	68	37	68	38	70	35	73	

these galaxies are found, it is unlikely that the results will depend very sensitively on the cosmological parameters (the situation is quite different for the quasars, which are visible out to much larger red-shifts). The models we have investigated in detail are the Einstein-de Sitter (σ_0 = $q_0 = \frac{1}{2}$), Milne $(\sigma_0 = q_0 = 0)$ and de Sitter $(\sigma_0 = 0, q_0 = -1)$ models. These are the fixed points in the σ-q plane, and correspond to asymptotic states of homogeneous, isotropic, pressure-free universes. For comparison, the results obtained for the steady state model are given in column 4. From the last row of Table 1 we see that for all these four models the total number of strong radio galaxies found in the farther region (b) is significantly larger than in region (a). The distributions do not differ greatly from model to model.

The incompatibility of the steady state model (in which evolutionary effects are not permitted) with the radio galaxy data is perhaps more serious evidence against that model than the distribution of the quasars¹, because doubts have frequently been raised as to the cosmological nature of the large red-shifts of quasars. Conversely, an important impetus to these doubts, the prospect of attributing the steep radio source counts entirely to the quasars^{18–20}, would be removed if the present results are confirmed by more accurate data.

To test whether the results could be significantly affected by the uncertainties in the estimated magnitudes, the optical magnitudes of the eighty-eight galaxies for which we have estimated the red-shift using equation (2) have been decreased by (i) one magnitude and (ii) two magnitudes (increasing the magnitudes merely reinforces the inequality between the totals for regions (a) and (b)). The corresponding numbers of sources found in regions (a) and (b) are shown in Table 2 for all luminosities greater than 10^{24} W (c/s)⁻¹ ster⁻¹. Because from Table 1 we see that the inequality between the totals in regions (a) and (b) is caused primarily by sources with luminosity greater than $10^{24\cdot9}$ W (c/s)⁻¹ ster⁻¹, the totals are also shown for this restricted range of luminosity.

The numbers of sources found in regions (a) and (b) are still significantly different, even if the optical magnitudes of all the galaxies are in error by 2 magnitudes in the same direction, for the higher range of luminosity.

$Log_{10}P > 23$ $Log_{10}P > 24.9$	58 36			60 37	82 68		50 27	71 57

A more likely situation is that errors of up to 1 magnitude exist, but in either direction, so that the totals found in Table 1 are probably not greatly in error. Rows 5 to 6 of Table 2 show the effect of changing the value of B in equation (2), which again does not alter the basic conclusion. Finally, because it may be argued that, in view of the paucity of red-shifts for galaxies with $19 \le V \le 20$, it is inadmissible to use an extrapolation of the form (2) in this range, row 6 shows the results obtained when attention is confined to galaxies with $V \le 19$ ($z \le 0.3$). Incompleteness of the identifications in the fainter ranges of optical magnitude would merely reinforce our conclusions; against this must be offset the greater possibility of incorrect identifications.

These preliminary results provide the strongest impetus for the completion of red-shift measurements of radio galaxies in the 3CR catalogue. The evidence seems very strong that, for consistency with the usual cosmological models, some evolutionary factor must affect the distribution of the strong radio galaxies. The effect is clearest for galaxies with radio luminosity greater than 1025.4 W (c/s)-1 ster-1, but, because such a small volume of space is visible for the lower ranges of luminosity, no clear effect would be expected for these anyway. Of the models proposed by Longair¹⁹ in his attempt to explain the Cambridge radio source counts, his model (d), density evolution of all sources with radio luminosity greater than $10^{26.8}$ W $(c/s)^{-1}$ ster-1, is definitely unsuitable. But his model (b), luminosity evolution of all sources with luminosity greater than 10^{25.4} W (c/s)⁻¹ ster⁻¹, is entirely in agreement with the present work (though Longair preferred to interpret this evolution as being caused by the quasars only). But it seems unproved that the evolution does not operate down to luminosities a factor of, say, 10 lower than this.

Further evidence of this evolutionary effect is that, if the thirty-four 3CR radio galaxies with luminosities less than $10^{25} \,\mathrm{W} \,(\mathrm{c/s})^{-1} \,\mathrm{ster}^{-1}$ are excluded, a number-count slope of about -1.9 is obtained for 3CR radio galaxies, as opposed to -1.55 reported by Veron²⁰ for all 3CR radio galaxies.

Possible Forms of Evolution

To test evolutionary hypotheses, the luminosity-volume test is easily modified; we investigate the distribution of "corrected" luminosity against "weighted" volume^{5,6}. The evolutionary hypotheses tested in ref. 6 for the quasars were

luminosity evolution

(i) negative power-law dependence on R(t),

$$\bar{P}(z) \propto (1+z)^{QL}$$

(ii) negative exponential dependence on R(t),

$$ar{P}(z) \propto \exp \left\{ (1+z_L) \cdot \left(1-rac{1}{1+z}
ight)
ight\}$$

density evolution:

(iii) negative power-law dependence on R(t),

$$\eta(z) \propto (1+z)^{Q_D}$$

(iv) negative exponential dependence on R(t),

$$\eta(z) \varpropto \exp \left\{ (1+z_D) \cdot \left(1-\frac{1}{1+z}\right) \right\}$$

where $\bar{P}(z)$ gives the behaviour with epoch of the luminosity of any particular class of sources, and $\eta(z)$ is the co-ordinate number-density of sources.

The advantage of evolutions of the form (ii) and (iv) is that they do not require arbitrary truncation of the evolving population to obtain a finite contribution to the integrated background radiation.

The values of the parameters Q_L , z_L , Q_D , z_D necessary to give consistency of the radio galaxy data with various

EVOLUTIONARY PARAMETERS FOR RADIO GALAXIES (RG) AND QUASARS (Q) Table 3.

cosmological models are given in columns 1 to 4 in Table 3, together with the corresponding values for the quasars, taken from ref. 2. There is remarkably close agreement of the parameters required for the exponential evolutions of both quasars and radio galaxies (columns 2 and 4). In view of the arbitrariness of the particular forms of evolution we have considered, this agreement cannot be taken as evidence of a link between radio galaxies and quasars. But if such a link is accepted (for example, ref. 21), then these forms of evolution seem very promising. consistency with radio-source counts to low flux-levels, and with the integrated radio background, will be discussed in subsequent papers.

Although our discussion has been confined to three particular relativistic models, similar results are found for all models in the range

$$0 \le \sigma_0 \le 3, -1 \le q_0 \le 3$$

It seems that for radio galaxies the evolutionary factor far outweighs any differences between the cosmological models. The explanation of this evolution must await more detailed knowledge of the structure of radio galaxies: whether, for example, they correspond to early or late stages in the life of a galaxy, and whether interaction with an intergalactic gas or magnetic field is an essential feature of their activity.

I thank Professor W. H. McCrea for advice and encouragement throughout the course of this work, which was performed during the tenure of a Science Research Council studentship at the Astronomy Centre, University of Sussex. Computing was performed by the Computer Centre, University of Sussex. Professor M. Schmidt made helpful criticisms.

Note added in proof. The present results, when combined with those of ref. 6, show that it is not possible to attribute the steep radio source-counts to observational bias, as claimed recently by D. L. Jauncey (Nature, 216, 877; 1967).

Mutagenic Capacity of Adenoviruses for Mammalian Cells

by H. F. STICH D.S. YOHN Department of Biology, McMaster University, Hamilton, Canada, and Viral Oncology Section, Roswell Park Memorial Institute, Buffalo, USA

Adenoviruses are mutagenic for mammalian cells. Viral replication, which results in a cytocidal effect, seems to be independent of a mutagenic effect caused by adenoviruses which initiate, but do not complete, a full replication cycle.

ALTHOUGH the actual frequency with which chromosomal anomalies occur in the human population is still unknown, the evidence in this article clearly indicates that karyotypic anomalies are aetiologically associated with a variety of human diseases. Thus there is a need to understand and to control the factors which are involved in the formation of abnormal chromosome complements. Ionizing and non-ionizing radiation and a great variety of chemicals have repeatedly been considered to be the chief cause of chromosome aberrations, whereas extensive attention has only recently been given to the mutagenic action of mammalian viruses1. Lack of knowledge concerning the mutagenic activity of viruses has been the result of the difficulties encountered in analysing and controlling the multitude of factors which are involved in virus host-cell interactions. In this article it will be shown that, in certain conditions, oncogenic and non-oncogenic

adenoviruses induce chromosomal aberrations which potentially lead to the formation of genetically abnormal cells.

Two different mammalian cell systems have been used in these studies: (a) human cells (AV-3, Hep-2 and HeLa) which favour the formation of infectious adenovirions; and (b) hamster cells (BHK-21 and primary cultures) which do not support a complete replicative cycle of certain adenoviruses²⁻⁵. Human adenovirus types 2, 4, 7, 12 and 18 and simian adenoviruses SA-7, SV-15 and SV-20 were tested. Of these, types 12, 18, SA-7 and SV-20 are highly oncogenic; adenovirus 7 is weakly oncogenic and the remainder, apparently, are not oncogenic.

Regardless of their oncogenic capacity, all adenovirus types which were examined induced a wide spectrum of chromosome aberrations in cultured cells of Syrian hamsters (Table 1). Chromatid breaks and exchanges com-

prised the chief types of aberrations found in cells infected with adenoviruses 12 and 18, whereas coiling deficiencies and metaphase arrest (C-mitosis) predominated in cultures infected with adenoviruses 2, 4, SV-15 and SA-7. In human cells, adenovirus infection leads to cessation of mitosis, clumping of interphase chromatin and disintegration of the host cell. Chromosome aberrations can be observed only in those infected human cells which are capable of entering division before onset of viral replication and mitotic inhibition.

An attempt has been made to estimate the influence of the viral dose on the incidence and type of chromosome aberrations (Fig. 1). Viral replication and the possibility of re-infection are two of the factors which usually interfere with quantitative evaluations. By employing cultured hamster cells in which most adenoviruses do not multiply, these difficulties were avoided. In these experimental conditions the incidence of chromosomal aberrations which were induced by each input multiplicity was a direct function of the viral dose. The accuracy of such studies, however, is not comparable with those studies which employ ionizing radiation or chemical mutagens. This is chiefly because of a lack of knowledge concerning,

for example, the proportions in a given virus preparation of infectious and of non-infectious virions and of virions unable to adsorb or to be uncoated properly.

Our results do indicate that adenoviruses, which propagate and induce clinical symptoms only in the natural or phylogenetically closely related hosts, are capable of interfering with the chromosome complement in an unrelated host in which viral replication is absent or rare. This observation suggests that chromosomal damage which is detectable at metaphase and which leads to daughter cells with abnormal karyotypes occurs in cells in which the viral replication cycle does not proceed beyond an initial stage. At present it is difficult to point to the precise stage at which the viral replication cycle in hamster cells ceases: T-antigen is formed whereas synthesis of some virion antigens and of viral DNA seems to be lacking2-5,8. If we assume that neither replication of viral DNA nor the transcription of the entire viral genome is necessary for the induction of chromosome aberrations, then adenoviruses with a damaged template should retain their capacity to interfere with the host genome. This assumption has been tested by examining the incidence of chromosomal aberrations induced in human and hamster cells by viruses impaired with ultraviolet light. It is known that UV-exposed adenoviruses lose their capacity to replicate faster than they lose their ability to induce T-antigen. Thus the replication cycle of UV-treated adenoviruses in human cells might be interrupted at a stage similar to that occurring in hamster cells which are infected with non-irradiated virus. UV-irradiated stocks of adenoviruses types 2, 4, and 18, which no longer replicate in human cells, retain their capacity to induce chromosome anomalies in hamster cells (Fig. 2) and human cells (Table 2).

The present claim concerning the mutagenic properties of adenoviruses would seem questionable without mentioning a few pitfalls which, if ignored, could easily lead to erroneous conclusions. A crude or semi-purified virus preparation usually contains various amounts of cell debris and viral sub-units. Chromosomal aberrations

[•] Purified by density gradient centrifugation in caesium chloride.

induced by these types of virus preparations could thus be the result of mutagens which are present in the cell debris.

The neutralization of viruses with specific antibodies, and purification of mature virions by density gradient centrifugation, are two useful methods for distinguishing between the mutagenic effect of infectious viruses and that caused by some non-viral elements. The data presented in Table 2 show that preparations of adenovirus 18 which have been treated with viral antibodies lose their capacity to induce chromosome aberrations. Highly purified virus preparations retain their capacity to interfere with chromosome complements. Another possible complicating factor is the presence of viruses associated with adenovirus (AAV) either in the adenovirus preparations or in the host cells10,11. Examination by electron microscopy did not reveal the presence of AAV in purified virus preparation or in infected cells. Thus it can be concluded that the chromosome aberrations mentioned here are the result of adenovirus infection and are not the result of the presence of an associated virus.

Although the mutagenic effect of viruses is comparable in many aspects with that of ionizing radiation or radiomimetic chemicals, there are several features which are unique to viral mutagenesis. First, the replication cycle of adenoviruses must be incomplete or else virus replication leads to cell death. Thus the cytocidal and the mutagenic effects of adenoviruses are mutually exclusive at the individual cell level. Second, chromosomal damage induced by adenovirus cannot be too severe or else loss of proliferative capacity or cell death could result. Finally, the addition of viral information, or part of it, to the infected cell represents a change in the genetic composition of the host cells. Thus cells which survive an adenovirus infection could have an altered genome because of the addition of the viral genome or because of an abnormal chromosome complement or both. In this connexion it is of interest to review antigenic and karyologic analyses of neoplastic cells induced by adenovirus 12 (refs. 12 and 13).

Neoplastic cells of primary or transplanted tumours induced by adenovirus 12 in Syrian hamsters do not yield mature virus particles which can be detected in the electron microscope, nor can infectious virions be recovered from these cells, \$\tilde{s}\$. All primary or transplanted neoplasms induced by adenovirus 12 which have so far been examined contain adenovirus T-antigen. This antigen is localized in fleck-like structures by immunofluorescence microscopy4.8 and is composed of bundles of fibres as revealed by immunoelectron microscopic techniques⁵. It has also been shown that these tumours contain a surface transplantation antigen which is specific for the adenovirus inducing it14. The capacity to synthesize T-antigen, which seems to be coded by the viral genome, is transmitted to most, if not all, daughter cells. This observation suggests that the viral genome, or at least the portion carrying the information for T-antigen, has become an integral part of the host cell. More direct evidence has been obtained from nucleic acid hybridization experiments indicating that the neoplastic cells retain 40-60 per cent of the viral genome¹⁵. Karyological studies have revealed an exceptionally high frequency of chromosomal aberrations in primary, transplanted and cultured neoplasms (Table 3). This persisting instability of the chromosome complement seems to point to the intracellular presence of a mutagen, which must be transmittable over many cell generations and also must be continuously synthesized. The formation of T-antigen in all the cells which show an increased frequency of chromosome aberrations suggests that T-antigen may function as the mutagen. At present it is difficult to prove or disprove this idea, particularly because even the nature of the T-antigen is unknown.

Table 3. THE PERSISTENCE OF CHROMOSOME ABERRATIONS IN AD. 12 INDUCED NEOPLASTIC CELLS OF SYRIAN HAMSTERS

	Chromosome aberrations (%)	Abnormal karyotypes (%)	No. of neoplasms analysed
Primary	33.7-62.5	64-89	10
Transplanted	32.0-46.8	100	-5
Cultured	50-0-59-5	100	6

At this point the old and controversial question concerning the significance of chromosomal aberration in the process of neoplastic transformation arises 18-19. controversy concerns the claim that chromosomal aberrations leading to abnormal genotypes are of primary importance in oncogenesis and the counter claim that chromosomal anomalies represent phenomena independent of, or superimposed by, the oncogenic process. The neoplasms induced by adenovirus 12 seem to exemplify a case which does not fit precisely into the chromosome concept of oncogenesis, nor does it prove the absence of any chromosome involvement. The great variety of abnormal karyotypes in this neoplasm and the continuous appearance of new ones12,13 suggest that the maintenance of the malignant property is not a function of a particular chromosome complement. Similarly one could argue that the formation of the T-antigen cannot be dependent on a particular karyotype. This absence of any detectable role of particular karyotypes in the established neoplasms does not exclude the possibility that chromosome aberrations could be involved in one of the initial stages of oncogenesis. The "open ends" of chromatid breaks, which tend to associate with other "open ends". could function as acceptors of the viral genome or part of it. This idea would be in agreement with the generally accepted concept that breaks are required for the incorporation of one DNA segment into another DNA molecule. In this connexion it is of interest to note the suggestion that viral DNA fragments could be more easily incorporated into the host genome than would the entire viral DNA (ref. 20).

Haemolytic Efficiency of Rabbit IgG Anti-Forssman Antibody and its Augmentation by Anti-Rabbit IgG

by
J. H. HUMPHREY
National Institute for Medical Research,
London, NW7

Complement dependent lysis of an erythrocyte can be achieved in optimal conditions by reaction of a suitable anti-lgG with a single molecule of lgG antibody on the surface of an erythrocyte. Optimal conditions require special precautions to avoid antibodies which prevent C' activation. For lysis of a sheep erythrocyte without augmentation, about 800 molecules of an lgG antibody were needed.

EVIDENCE has been published^{1,2} that a single molecule of rabbit IgM antibody against the Forssman antigen on the surface of sheep erythrocytes can suffice to activate guinea-pig complement (C') so as to lead to a site of irreparable damage and cell lysis. In the case of IgG antibodies it was suggested¹ that C' activation and lysis only occur when two antibody molecules become attached to the cell surface at adjoining sites, and indirect evidence has confirmed that interaction of two such antibody molecules is needed³. The maximum number of IgG antibodies which can attach to a sheep erythrocyte is about 600,000 and, with certain assumptions, the number of molecules which must be attached so as to give an even chance that two will be on adjacent sites can be calculated to be about 800 (ref. 4). Direct measurements of the number of IgG anti-Forssman molecules which are required for C' dependent lysis of an erythrocyte gave figures of this order though somewhat larger¹.

Knowledge concerning the number of IgG antibody molecules which can attach to an erythrocyte with or without causing C'-dependent lysis is also of interest in connexion with the development of plaques of haemolysis around cells making antibody in gels or gums containing erythrocytes^{5,6}. Lysis is normally caused mainly or wholly by IgM antibody, but, by additional treatment with a suitable antibody against IgG, erythrocytes coated with IgG antibody became susceptible to lysis by C' (refs. 7 and 8). If several molecules of anti-IgG interact with each molecule of attached antibody and so activate sufficient C' at each site of attachment to cause a local haemolytic "hit", a single IgG antibody on the cell surface should suffice to lyse the cell by this technique. On this assumption, comparison of the number of IgG antibody molecules/cell required for haemolysis with and without augmentation by anti-IgG, would yield an independent estimate of the number of attached IgG molecules which are required to lyse a cell by means of C' alone. The experiments which are described later were designed to test these assumptions.

Fresh guinea-pig serum which had been absorbed three times at 0° C with sheep erythrocytes was used as the source of C'. Purified rabbit IgG anti-Forssman antibody was prepared from serum of rabbits which were hyperimmunized by intravenous injections of boiled sheep cell stroma⁹, by absorption on to formolized sheep erythrocytes, elution at pH 10·6, and further separation from

IgG by gel filtration through 'Sephadex G-200' (Pharmacia, Uppsala) followed by repeated centrifugation through a gradient of 10-30 per cent sucrose⁴. After trace labelling with ¹²⁵I, more than half of the IgG specifically bound to sheep erythrocytes. No detectable IgM or IgA was present.

The purified antibody was titrated for its capacity to lyse sheep erythrocytes in a standard system used for all these tests, containing 10° erythrocytes/ml. and a 1/100 dilution of C' in veronal buffer saline with 0·1 per cent gelatine and 0·0005 molar magnesium and 0·00017 molar calcium (VBS)°. The dilution which caused 50 per cent lysis after incubation for 1 h at 37° C was estimated by centrifugation of the mixtures in the cold and measurement of the haemoglobin in the supernatant by its OD at 540 mμ.

Antisera were obtained from horses, goats and guineapigs which had been immunized with purified rabbit IgG (in Freund's complete adjuvant, followed in some instances by IgG adsorbed on aluminium hydroxide). These sera were not absorbed with rabbit Ig light chains, and contained antibodies to light as well as to IgG heavy chains. They had no demonstrable haemolytic antibody against Erythrocytes were mixed with a sheep erythrocytes. dilution of IgG anti-Forssman antibody 1/50th of that sufficient to lyse the erythrocytes by itself. After incubation at 37° C for 10 min, C' was added, followed by varying dilutions of the antisera. Incubation was continued for 1 h and the degree of haemolysis was measured. control tubes with IgG antibody and C' alone, lysis was less than 5 per cent. The horse and goat antisera caused either no or only partial additional haemolysis over a wide range of dilutions. Some, but not all, of the guinea-pig antisera caused complete lysis, however. It seems probable that the variable potency of the antisera to augment haemolysis depended on the extent to which they contained antibodies capable of activating guinea-pig C'. Most horse and goat antibodies are known to activate guinea-pig haemolytic C' poorly or not at all, and even guinea-pig 7S antibodies have been shown to be separable into two distinct immunoglobulin components, γ_2 - and γ_1 -, of which only γ_2 - activates C' (ref. 10). These components were therefore separated from the guinea-pig antisera by chromatography on DEAE cellulose¹¹. The γ_2 -immunoglobulin preparations were apparently pure as shown by immunoelectrophoresis against an antiserum against mixed guinea-pig globulins, but the γ₁- preparations contained several contaminating proteins other than Y2immunoglobulin.

Haemolysis tests with guinea-pig γ₂-anti-rabbit IgG were set up as follows using a separate pipette for each dilution step in order to avoid dilution errors. Sets of tubes containing washed sheep erythrocytes and suitable two-fold dilutions of the rabbit IgG anti-Forssman antibody were incubated for 30 min at 37° C with occasional shaking. To each set C' was added next, followed immediately by one of the chosen dilutions of guinea-pig γ_2 anti-rabbit IgG. After further incubation for 1 h the tubes were chilled and the degree of haemolysis was measured. Controls were included to allow for absorption at 540 mu of complement alone and to exclude any haemolysis of unsensitized cells by anti-rabbit IgG. The results of three experiments using different preparations of guinea-pig γ_2 anti-rabbit IgG, prepared from separate sera, are shown in Table 1. The augmentation of lysis increased with increasing concentration of anti-rabbit IgG to a maximum of 425-fold in the first experiment, 1,300fold in the second and 670-fold in the third.

Table 1. Augmentation of C'-dependent haemolysis by anti-igg

	Dilution of gpig antibody	Dilution of rabbit anti- Forssman IgG required for 50% lysis	Augmentation ratio

The 50 per cent haemolytic end-point for sheep erythrocytes of rabbit anti-Forssman IgG was measured in the presence of varying dilutions of the γ_2 -globulin fractions prepared from guinea-pig anti-rabbit IgG. Different preparations of anti-rabbit IgG were used in the separate experiments. The final concentration of erythrocytes was 10^8 per ml. and of C' was 1/100.

According to the assumptions made earlier, anti-rabbit IgG was not expected to augment lysis by rabbit IgM anti-Forssman antibody. This was confirmed by pretreating sheep erythrocytes with an amount of purified IgM antibody which was sufficient to cause 65 per cent haemolysis in the presence of C' alone. It was found that the extent of lysis was unaffected by the addition of sufficient anti-Ig to augment almost 500-fold the lysis by IgG anti-Forssman antibody.

Unlike γ_2 antibody no preparation of γ_1 guinea-pig antirabbit IgG caused haemolysis of erythrocytes which had been sensitized with sublytic amounts of rabbit IgG Forssman antibody, even though the concentration of antibody in the γ_1 -globulin was considerably greater than that in the γ₂-globulin when compared in terms of precipitation with rabbit IgG in gel diffusion tests. Furthermore, if the γ_1 - and γ_2 - anti-rabbit IgG from the same serum were mixed, the haemolytic effect of the Y2-antibody on erythrocytes sensitized with rabbit IgG was inhibited. In some guinea-pig antisera the γ₁-antibody present was sufficient to prevent completely the haemolytic augment-

ing effect of γ_2 -antibody present in the same serum. The results obtained with goat and horse anti-rabbit Ig are set out in Table 2. Most of the antisera were able to cause partial augmentation of lysis, and there was a definite optimum concentration for this effect; there was no evident correlation, however, with the total amount of precipitating antibody present. view of the evidence presented here that guinea-pig γ_1 -antibody inhibits the augmenting effect of γ_2 -antibody, these findings strongly suggest that the goat and horse antisera also contain a mixture of antibodies, part of which can activate guinea-pig haemolytic C' and part cannot, but are rather inhibitory. It has indeed been

reported by Nakamura and Katsura¹² that γ₂-globulin but not T-globulin from horse anti-diphtheria toxin will fix guinea-pig haemolytic C' in the presence of antigen, and this has been confirmed by Raynaud and his colleagues 13 .

Table 2. Augmentation of haemolysis by sublytic amounts of rabbit igg anti-forssman antibody produced by goat and horse anti-rabbit ig

	Anti-RGG	%	Lysis (of sheep c	ells in pre	sence
Nature of	content	of various dilutions of antiserum				
${f antiserum}$	(mg Ab/ml.)	1/50	1/500	1/5,000	1/50,000	1/500,000
Goat 3/55	8	0	0	0	0	0
Goat 2/62	2	44	83	68	17	0
Goat "Bishop"	3	65	92	75	50	Not tested
Horse 253	Approx. 8	1	34	42	27	9
Horse R.P.	Approx. 8	0	34	25	13	0

Sheep erythrocytes were sensitized with 1/50th the amount of rabbit IgG anti-Forsman antibody required for 50 per cent haemolysis, and were then incubated in the presence of C' for 1 h at 37° C. None of the antisera caused lysis of unsensitized erythrocytes under the same conditions.

The haemolytic potency of rabbit IgG anti-Forssman antibody could be augmented 470-1,300 (mean 820) fold by various preparations of guinea-pig γ_2 anti-rabbit Ig under otherwise identical conditions. If two molecules of rabbit IgG antibody, adjacent on the erythrocyte surface, are required for activation of C' in order to produce a site of damage, whereas a single molecule suffices when it acts as a focus for subsequent attachment of anti-IgG, this finding would imply that there must be about 800 molecules on the surface for two to be effectively adjacent. An assumption implicit in this calculation is that the addition of anti-IgG does not alter the number of Forssman antibody molecules which are attached to the erythrocyte surface. This is probably justified because the IgG Forssman antibody used in this study was highly avid4 and a very large excess of Forssman sites was present, so that virtually all of the antibody will have been bound to erythrocytes before the anti-IgG was added. When another and less avid purified IgG Forssman antibody was used, the maximum augmentation of lysis by the same anti-IgG preparations was only 80 fold.

The very close agreement between the mean value of 820 and the calculated value of approximately 800 attached IgG antibody molecules/cell required for lysis without augmentation is gratifying but probably fortuitous and the highest value, 1,300, may be the most significant. Nevertheless, taken together, the findings indicate that lysis of an erythrocyte can—under optimal conditions—be achieved by reaction of a suitable anti-IgG with a single molecule of IgG antibody on the surface. In view of the presence which has been shown of an inhibitory antibody in antisera to IgG prepared in guinea-pigs, and of its probable presence in goat and horse antisera, optimal conditions are unlikely to be achieved without special precautions. Fortunately rabbit antisera, which are often used as the source of antibody against immunoglobulins in studies on augmented haemolytic plaque formation, contain predominantly antibodies which can activate guinea-pig C'.

ASTRONOMY

Cosmological Models containing both Radiation and Matter

JACOBS¹ has recently compared two types of cosmological models which change from a radiation-like model for early time to a matter-like model for recent time. The radiation in these models is in thermal equilibrium with the matter and the photons, neutrons and electrons are not treated separately (as they are, for example, in ref. 2). In a flat space (k=0), the function R(t) of the line element

$$ds^{2} = c^{2}dt^{2} - R^{2}(t) \left\{ \frac{dr^{2}}{1 - kr^{2}} + r^{2}(d\theta^{2} + \sin^{2}\theta d\varphi^{2}) \right\}$$
(1)

changes from being like $At^{1/2}$ for early time to being like $At^{2/3}$ for recent time. The two models Jacobs discusses will here be called model I and model II. R(t) is given in model I by

$$t/\tau = [(R/R_0) - 2S_0] [(R/R_0) + S_0]^{1/2} + 2 S_0^{3/2}$$
 (2)

where

$$\tau \equiv \left(\frac{3}{2} \times c^4 \,\rho_{m,0}\right)^{-\frac{1}{2}}, \, S_0 \equiv \rho_{r,0}/\rho_{m,0} \tag{3}$$

and in model II by

$$\log R(t) = 2 \left([3t + \beta^{-1}(1 - e^{-\beta t})]^{-1} dt + \text{constant} \right)$$
 (4)

where β is a constant3. Here the density and pressure are

$$\rho = \rho_r + \rho_m, \ p = p_r = \frac{1}{3} \rho_r c^2 = \frac{1}{3} a T^4$$
 (5)

where ρ_r and ρ_m are the density of radiation and matter, respectively, p_r is the pressure of radiation, the pressure of matter is put equal to zero, a is Stefan's constant and T is the radiation temperature. Also, for a Hubble parameter

$$H = \dot{R}/R \tag{6}$$

we define

$$E_m = (\dot{\rho}_m + 3H\rho_m)c^2 \tag{7}$$

and

$$E_r = (\dot{\rho}_r + 4H\rho_r)c^2 \tag{8}$$

so that the conservation equation gives

$$E_m + E_r = 0 (9)$$

 E_m and E_r were first defined by Davidson⁴ and are the total net rate of transfer of radiation energy per unit volume into matter energy and vice versa. A zero subscript denotes the present epoch. The present value of Tis of the order of 3° K from the measurement of the isotropic microwave background first found by Penzias and Wilson⁵ and Roll and Wilkinson⁶. This is believed by many to be a remnant of the initial "big-bang" or fireball''.

For the model I,

$$E_{\tau} = E_{m} = 0 \tag{10}$$

so that

$$\rho_m R^3 = \text{constant}, \ \rho_r R^4 = \text{constant}$$
 (11)

and for the model II,

$$E_r = -\rho_r/\chi, \ \chi^{-1} = \frac{3\beta t - 1 + e^{-\beta t}}{3\beta t + 1 - e^{-\beta t}}. \ \beta$$
 (12)

so that E_m is greater than zero for all t. As Jacobs points out, the model I is given by Chernin' in a different form.

As far as I know, the first analytical solution, with equation (10) holding, was given by Alpher and Herman⁸ for the space of negative curvature, and this solution is re-used by these authors together with Gamow in a recent communication⁸. The corresponding k=0 solution in their notation is (R. A. Alpher, private communication)

$$t = \frac{2}{3\gamma \rho_{m}^{2}} \left[(\gamma \rho_{r}^{*} + \gamma \rho_{m}^{*}L)^{3/2} - 3\gamma \rho_{r}^{*} (\gamma \rho_{r}^{*} + \gamma \rho_{m}^{*}L)^{1/2} + 2(\gamma \rho_{r}^{*})^{3/2} \right]$$
(13)

(which is the same as equation (2)) and the k=+1 solution is also given in ref. 9, when $K_2^{1/2}=ic/R_0$ is used in equations (13)-(15) of that communication, though the authors do not mention this because they are interested only in the k=-1 case. It can also be shown that these $k=\pm 1$ solutions are the same as those given by Chernin. A solution similar to that of equation (2) was also given by Dautcourt (private communication). Practically all writers in this field and in the field of cosmological element production assume equation (10).

For the model I, Chernin obtained formulae for the red-shift, z, and for other observable quantities but in inexact form. I have been able to find another way of expressing the solutions so that exact forms of z and of the [m,z] relation can be easily calculated 10. This is done by writing the solutions in terms of the parameter

$$\varepsilon = p/\rho c^2 \tag{14}$$

so that

$$R = A (1 - 3\varepsilon)/\varepsilon \tag{15}$$

(A = constant) from (5) and (11). For example, for k = 0, the [m,z] relation is

$$m_{\text{bol}} = 5 \log_{10} (1+z) \frac{2}{1-3\varepsilon_0} \left\{ 1 - \left(\frac{1+3z \, \varepsilon_0}{1+z} \right)^{1/2} \right\} + c \quad (16)$$

For small z, and for ε_0 small compared with 1, this reduces to

$$m_{\text{bol}} = 5 \log_{10} 2(1+z) \{1 - (1+z)^{-\frac{1}{2}}\} + c$$
 (17)

which is the equation given by Mattig¹¹ $(q=\frac{1}{2})$. It is interesting to compare the value of the red-shift, z, for the Einstein-de Sitter model $(R(t) = At^{2/3})$ with the value given by this model for a particular (non-recent) value of t_1 (the time of light emission). Partridge and Peebles¹² assess the general possibility of observing distant, newly formed galaxies which go through a stage of high luminosity at an epoch of

$$t_p \sim 1.5 \times 10^8 \text{ yr} \tag{18}$$

and they state that this epoch corresponds to a red-shift in the range 10 to 30 for various cosmological models. We will use a value of $t_1 = 4.8 \times 10^{16} \sec \sim t_p$. For the Einstein-de Sitter model

$$1+z = \frac{S_0}{S_1} = \left(\frac{t_0}{t_1}\right)^{2/3} \tag{19}$$

 $H_0t_0=2/3$ and, for $H_0=3\cdot2\times10^{-18}~{\rm sec^{-1}}$ and the assumed

$$z = 11.3 \tag{20}$$

For model I

$$t = \frac{2}{3} \frac{AB}{c} \left\{ e^{-3/2} \left(1 - qe \right) + 6\sqrt{3} \right\}$$
 (21)

 $(\beta = constant)$

$$1+z = \frac{S_0}{S_1} = \frac{1-3\varepsilon_0}{1-3\varepsilon_1} \cdot \frac{\varepsilon_1}{\varepsilon_0}$$
 (22)

and

$$H = \frac{c}{AB} \frac{\varepsilon^{3/2}}{(1 - 3\varepsilon)^2}$$
 (23)

For $T_0 = 3^\circ$ K

$$\rho_{r,0} = 6.8 \times 10^{-34} \text{ g/cm}^{-3} \tag{24}$$

and, with

$$\varkappa \rho_r c^4 = q H^2 \varepsilon \tag{25}$$

$$\varepsilon_0 = 1.24 \times 10^{-5} \tag{26}$$

so that, from equation (22)

$$c/AB = 1.53 \times 10^{-4} \tag{27}$$

With t_1 as before, equation (21) now gives

$$\varepsilon_1 = 1.53 \times 10^{-4} \tag{28}$$

so that, from equation (23)

$$z = 11.3 \tag{29}$$

Thus the zero pressure, Einstein-de Sitter model, is accurate enough for observations down to a red-shift of light from the youngest galaxies. Also, for $z \leq 11.3$, there is no real difference in the two [m,z] relations (16) and (17).

The model II fits in with equation (4.29) of Davidson and Narlikar's communication13, that is

$$\dot{\rho}_r + 4H\rho_r = S - \rho_r/\chi \tag{30}$$

where S(t) is the rate of emission of radiation from unit volume, and $\chi(t)$ is a frequency averaged mean free time between the emission and absorption of a photon, though only with S=0. Thus the model may be claimed to be one for a universe with radiation from a primeval bigbang, but one in which the matter does not emit radiation. With $E_r = E_m = 0$,

$$S=0, \chi=\infty \tag{31}$$

or

$$S = \rho_r/\chi \tag{32}$$

What is wanted is either a model with $E_m < 0$ for all t, or, better still, one with $E_m > 0$ for early t and < 0 for recent t. Many models of this type for spaces with $k=0, \pm 1$, and also the general theory of models with $\frac{1}{3} \ge \varepsilon \ge 0$ and $E_m \ge 0$, have been developed, and work in this field will be described in a future paper. Part of this work leads to

$$E_m \propto - \left[\dot{\mathbf{\epsilon}} + \varepsilon (1 - 3\varepsilon) H \right]$$
 (33)

which gives a condition on ε for the required sign of E_m . The solution of

$$E_m = 0 = \stackrel{\bullet}{\varepsilon} + \varepsilon (1 - 3\varepsilon)H \tag{34}$$

is equation (15) as expected.

The most physically satisfactory form of a seems to be

$$\varepsilon = \frac{1}{3} (1 + \mu t)^{-n} \tag{35}$$

(μ , n positive constants). Here, for all t, $E_m>0$ for small μt . For k=0 and n less than about 2/3, $E_m<0$ for recent t.

Jacobs comments on the late stage of domination by the matter in the model II. Any model with $E_m > 0$ will become dominated by the matter at a time after the corresponding time in the $E_m = 0$ model and this will itself be after the corresponding time in an $E_m < 0$ (for recent t) model.

Davidson⁴ showed that for $R \propto t^n$

$$E_m \varpropto n(2n-1) \ (3n-2) \tag{36}$$

which is <0 for $\frac{1}{2} < n < \frac{3}{3}$. from which it would appear that, as R(t) changed from an $n = \frac{1}{2}$ like model to an $n=\frac{2}{3}$ like model for t increasing, E_m would always be < 0, but this is by no means true. He also points out13 that a disappointing feature of this work is that "the physical character of cosmic evolution seems to be very sensitive to the chosen R(t) function.

I thank Dr N. W. Taylor and also those with whom I

have corresponded for useful discussions on this work.

PHYSICS

Ultrasonic Attenuation in the Pre-melting Region

THE solid-liquid transition, a co-operative phenomenon, should be quantum mechanical in origin. There have been a number of phenomenological treatments but so far no quantitative microscopic description of the interactions responsible. Plausibly, the source of the transition may be sought in the lattice dynamics solution for the eigenvalues in the anharmonic solid near the melting point. In the pre-melting region, as the anharmonicity of the interatomic forces increases, phonon-phonon scattering will be enhanced. Experimental evidence for this is Ultrasonic waves, although much lower in frequency, have the same nature as lattice vibrations; the attenuation of an ultrasonic beam, directly measur-

able, provides detail of phonon interactions.

The attenuation of longitudinal 10 Me/s ultrasonic waves has been studied by the pulse-echo technique in the pre-melting region of polycrystalline In₂Bi, a convenient material (melting point, 89°C) for preliminary measurements. Some details of the apparatus are given in ref. 1.

From room temperature to 87.5°C the attenuation rose by only 0·1 dB/μsec, but over the last degree before the melting point a rapid increase was extant, as shown in Fig. 1. On cooling, some hysteresis was observed; but the original value of attenuation was regained within about 2° C of the melting point. Results were reproducible. At no time was the temperature raised high enough for melting to ensue. Similar results have been observed during experiments, still in progress, on indium single crystals of 99.9999 per cent purity; the effect does not seem to result from specimen inhomogeneity or grain boundary melting.

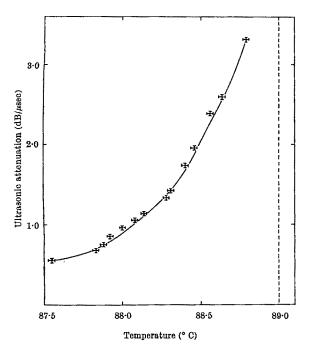

Fig. 1. Ultrasonic attenuation at 10 Mc/s near the melting point (89° C) in ${\rm In_2Bi.}$

Insight into the phenomenon can be gained by considering the contribution to the ultrasonic attenuation from the viscous drag of the lattice phonons^{2,3} in the condition that the thermal phonon mean free path is small compared with the sound wavelength ($\omega \tau_{th} \ll 1$). The phonon frequencies are modulated by the sound

Table 1. Velocity of Longitudinal sound waves in In₂Bi
Temperature (°C)
$$-269$$
 -198 20.5 77 85 [88.5
Velocity 2.63 2.56 2.43 2.40 2.38] 2.38 ($\times 10^5$ cm/sec)

wave; phonon-phonon interactions, dependent on anharmonicity, then bring the system back to thermal equilibrium; the sound wave driving the process is damped. This seems to be the predominant mechanism for ultrasound absorption in the pre-melting region. Woodruff and Ehrenreich's find that the attenuation al of an ultrasonic wave of angular frequency ω is given by

$$\alpha_L = \frac{8.68 C_{\nu}. T. \gamma^2 \tau_{th} \omega^2}{3 \rho v^3} dB/em \qquad (1)$$

where \gamma is an average Gruneisen constant of the order of unity. In terms of the thermal conductivity $K = 1/3 C_V$ $v^2 \tau_{\rm th}$) this becomes

$$\alpha_L = \frac{8.68 \,\gamma^2 \,\omega^2 \,KT}{\rho v^5} \,dB/em \qquad (2)$$

The velocity of longitudinal sound waves shown in Table I does not alter within the experimental accuracy of ± 0.5 per cent in the pre-melting region. At temperatures greater than the Debye temperature the thermal conductivity is approximately proportional to T^{-1} ; therefore KT and, in consequence, α_L (~0-1 dB/cm) should be independent of temperature. A sharp rise in the thermal conductivity of both pure metals and alloys, however, has been observed near the melting point, and the specific heat anomaly is well known^{5,6}. Thus the ultrasonic attenuation reflects the rise in the specific heat. The interaction takes place within the entire assembly of the thermal phonons, rather than with the individual thermal modes. Enhancement of ultrasonic damping probably results from a rapid increase in anharmonicity of the lattice forces near the melting point.

THE SOLID STATE

Breakdown of Passivity of Stainless Steel by Halide lons

METALS and alloys which are resistant to corrosion usually depend for their resistance on the formation and maintenance of thin films (commonly between 5 and 200 Å thick) of passivating oxide. The breakdown of such films by "aggressive" anions such as chloride, at sufficiently positive anode potential and at sufficiently high temperature, is often responsible for the failure of such alloys, because it usually leads to serious pitting of the bared metal.

Many mechanisms for the breakdown action of chloride ions have been suggested: they include (1) the penetration of the small chloride ions through pores1 in the oxide film—if actual pores are not present, weak places2 might suffice; (2) the displacement of the (very thin) film by adsorption of chloride ions^{3,4}; (3) anion exchange between oxide ions and chloride ions; (4) migration of chloride ions inwards through the oxide lattice5; and (5) peptization of the oxide film by a strong negative charge caused by adsorbed anions. None of these mechanisms has been shown by experiment to be more than plausible for any particular case, and in particular there is very little kinetic evidence about the rate of breakdown and the factors influencing it.

We have studied the kinetics of breakdown of anodically formed passivating films on 18 chromium-8 nickel austenitic stainless steel by chloride and bromide ion. Anodic passivation was first achieved by polarizing the alloy specimen in slow flowing deaerated 0.01 molar sulphuric acid (pH about 2) or 0.15 molar phosphate buffer solution (pH 7) at a fixed potential controlled by a poten-When the anode current density had become steady (about 10-6 amp/cm2), the flow was replaced by a solution similar in all respects except for an addition of sodium chloride or bromide. We expected that a sufficient addition would lead to either a slow, though accelerating, increase of anode current density caused by slow contamination of the oxide lattice by anion exchange (suggestion (3)) or by migration (4), or an almost immediate large increase caused by penetration of pores or weak places (1), adsorption displacement (2) or peptization (5). Neither of these kinds of change occurred; in fact, the overall anode current density after the chloride addition remained constant for an induction period, τ , of from a few seconds to several hours, depending on the chloride concentration, $c_{\rm Cl}$ -, the anode potential, E, and the absolute temperature, T, and then very rapidly increased by several times (Fig. 1) with the onset of visible pitting. Evidently, the anode current density at the very small pit or pits increased by several orders of magnitude compared with the current density of the passivated surface.

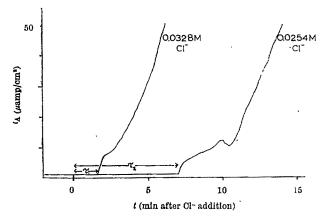

Fig. 1. Typical current-density/time curves, 18-8 stainless steel in sulphuric acid, showing effect of chloride addition. 25° C; pH 2-05; $e_H+800~\rm mV$.

The relation between log τ and log c_{Cl} at 25° C for three anode potentials is shown in Fig. 2. If we suppose that $1/\tau$ is an approximate estimate of the rate of the breakdown process, whatever it may be, then the slope of the log $\tau/\log c_{\text{Cl}}$ plots shows that the rate is proportional to the *n*th power of the chloride ion concentration, where n lies between 2.5 and 4.5. From the separation of the three lines, we find that $(-\partial E/\partial \log \tau) c_{\text{Cl}}$, τ is in the range 250 to 450 mV. Similar experiments at 40° C showed that τ is decreased by more than two orders of magnitude by the modest temperature rise from 25° C. or

$$(-\partial \log \tau/\partial \frac{1}{T})c_{\text{Cl}}^{-},_{E}$$

is about 1.2×10^4 , leading to an experimental apparent energy of activation of some 60 kcal/mol. Experiments with bromide additions gave very similar results; the rate dependence on $c_{\rm Br}^-$ showed n between 4 and 4.5, and $(-\partial E/\partial \log \tau)c_{\rm Br}^-$, T was around 30 to 70 mV.

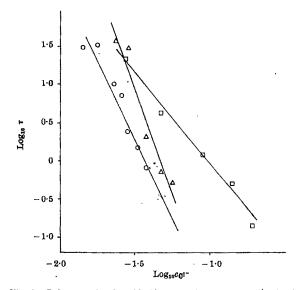

Fig. 2. Influence of added chloride concentration, c_{Cl}-, on induction period before breakdown, τ. 25° C; pH 2·05. Ο, 800 mV (nhe); Δ, 600 mV (nhe); Π, 400 mV (nhe).

The sharp dependence of the rate of the breakdown process on halide-ion concentration, anode potential and temperature shows at once why notional values of these factors have often been estimated, and indeed quoted in the specifications of resistant alloys; a particular alloy is resistant, say, up to "a chloride concentration of 0·1 molar", "a breakdown potential of +0·8 V (nhe)", "a temperature of 50° C", when the other two factors are kept at constant values. The sharp dependences of the rate of the breakdown process imply (in this illustrative example) that the onset of breakdown, although long delayed at the values given, could be rapid at, say, 0·2 molar chloride, or at +0·9 V (nhe), or at 60° C.

Further, the linear dependence of rate on $c_{CI-,Br-}^n$ where n=2.5 to 4.5, and the very high apparent activation energy, about 60 kcal/mol, show that the transition state in the breakdown process involves 2.5 to 4.5 halide ions* and has a very high energy. This rules out simple anion exchange or migration as rate-determining stages in breakdown. We therefore think that the breakdown process can best be described as follows. Three or four halide ions jointly "adsorb" on the oxide film surface around a lattice cation—one next to a surface anion vacancy for preference. The transitional complex thus formed will be of high energy and the probability of its formation at any instant will be very small. But, once formed, the complex can readily and immediately separate from the oxide ions in the lattice, the cation dissolving in the solution, very much more readily than the nonor aquo-complexed cations present in the film surface in the absence of halide ion. Under the anodic field, a further cation comes up through the film to replace the dissolved cation—the field at constant anode potential increases at the "thinned" point of the film; but arriving at the film/solution interface, it finds, not stabilizing oxide ion formed from water (nor, in de-aerated solution, oxygen molecules2), but several halide ions, so that the "catalytic" process, once begun, has a strong probability of repeating itself, and of accelerating because of the increasing electrostatic field. Thus, once localized breakdown starts with the initial transitional complex, it accelerates "explosively".

The process we have just suggested contains elements from hypotheses (1), (2), (3) and (4), and depends primarily on the high polarizability (in the electrostatic sense) of chloride or bromide ion, which promotes adsorption.

^{*} Note that values of n such as 20, which could be given no physical meaning, are not found.

The activation energy of the process is, of course, reduced by more positive anode potentials (much as in a simple charge-transfer process) and the probability of formation of the high-energy transitional complexes increases with rise of temperature, in the usual way.

CHEMISTRY

Microwave Spectra and Structures of Isothiazole, 1,2,4-Oxadiazole and **Imidazole**

ROTATIONAL spectroscopy has proved a powerful method of studying the structures of heterocyclic molecules 1-6. We have extended work of this type to molecules of isothiazole, 1,2,4-oxadiazole and imidazole.

Spectral assignments followed established lines, absorptions being observed for J values between 0 and 18 and in general for both A and B components of the dipole To observe the spectra of imidazole, the moments. sample and absorption cell were maintained at about 50° C to provide sufficient vapour pressure. Rotational constants were derived as follows (in Mc/s)

	\boldsymbol{A}	$\boldsymbol{\mathit{B}}$	c
Isothiazole 1,2,4-Oxadiazole Imidazole	8,275·52 ± 0·1 10,337·37 ± 0·2 9,725·06 ± 0·2	$5,846 \cdot 24 \pm 0 \cdot 05$ $10,092 \cdot 66 \pm 0 \cdot 1$ $9,373 \cdot 92 \pm 0 \cdot 2$	3,424·21 ± 0·05 5,103·33 ± 0·1 4,772·02 ± 0·2
N-Deutero- imidazole	9.668-31 + 0-2	8.699-39 ± 0-2	$4.578 \cdot 43 \pm 0 \cdot 2$

The moments of inertia show that all the molecules are planar, the small inertial defects being close to those found for furan¹, pyrrole², isomeric oxadiazoles³,⁴, thiazole⁵ and pyrazole⁶. The moments of inertia of imidazole are somewhat larger than for the molecular dimensions found by X-ray diffraction in the crystalline state?. This lack of agreement is not unexpected in view of the strong intermolecular interactions, and the short CH distances, reported in the solid. The effect, on the constants, of deuteration of the imino group allows the imino hydrogen to be located in the inertial axis frame; for any acceptable model this means that the A axis in imidazole makes an angle of about 28° with the NH bond. A study of numerous models with reasonable structure parameters suggests that this axis intersects the NC bond joining the 1 and 2 positions.

Nuclear quadrupole hyperfine structure was resolvable in all these spectra. For isothiazole, the coupling constants in the inertial axes are (in Mc/s):

$$\chi_{a\dot{a}} = 1.05 \pm 0.2$$
 $\chi_{b\dot{b}} = -2.42 \pm 0.1$ $\chi_{cc} = 1.37 \pm 0.3$

These are acceptable values in view of the findings for similar cases and the approximately known directions of the A and B axes in the molecule. For 1,2,4-oxadiazole, well resolved splittings, caused by the two non-equivalent nitrogen nuclei, occur. Although the coupling constants for the different nuclei may clearly be of comparable magnitude, an analysis, in terms of individual coupling constants, should be possible and is proceeding. expect that the hyperfine structures for imidazole will be

similarly analysed with anticipated improvements in resolution.

Analysis of Stark effects for a number of transitions of each substance leads to the following preliminary values of the dipole moment components (in \bar{D})

	$\mu_{\mathbf{a}}$	μъ	μ (total)
Isothiazole	1·1 ± 0·1	$2 \cdot 2 \pm 0 \cdot 1$	$2.4_4 \pm 0.2$
1,2,4-Oxadiazole	1.2 ± 0.2	0.2 ± 0.2	1.2 ± 0.3
Imidazole	3.7 ± 0.3	0.0 ± 0.3	3.8 ± 0.1

Because in isothiazole the A axis must approximately bisect the C-S-N angle, these data roughly define two possible lines of action of the total dipole in the molecule. The total moment agrees well with a recent determination from dielectric measurements. For 1,2,4-oxadiazole the moment found is notably less than those of the other oxadiazoles. Unpublished molecular orbital calculations by Davies and Mackrodt show that this difference is theoretically predictable and give good agreement with the moment found here. The dipole moment of imidazole has been given rather scattered values from dielectric experiments. Our result is close to the lower limit of the values obtained in solution and agrees closely with the moment calculated theoretically by Brown and Coller¹⁰. From the experimental A and B components of the moment in imidazole, the line of action of the moment is found to make an angle of approximately 13° with the A axis. This line of action can only agree well with that predicted by Brown and Coller¹⁰ if the A axis intersects the N-C bond joining positions 1 and 5, but this evidence may not be strong enough to compel a preference for this orientation of the axes.

It is clear that much fuller information about the orientation of axes of inertia, lines of action of dipole moments and axes of quadrupole coupling tensors will follow from extended studies, in progress or planned, involving isotopic forms of these molecules. Refinement of the Stark measurements will require allowance for quadrupole splittings and, in the case of 1,2,4-oxadiazole and imidazole, for quartic Stark effect corrections. Such studies promise exceptionally full data on both electron distributions and internuclear distances for comparison with the results of extensive theoretical treatments.

This research was sponsored, in part, by a grant from the Air Force Office of Scientific Research through the European Office of Aerospace Research (OAR), US Air Force. We thank Dr Ronald Slack for the gift of isothiazole, Dr C. Moussebois for a sample of 1,2,4-oxadiazole and the Science Research Council for a research grant. Two of us (A. W. and J. H. G.) also thank the Council for research studentships.

Thermal Conductivity of Glycine

RECENTLY it has been suggested 1-3 that electron spin resonance studies of irradiated amino-acids reveal thermal effects as well as directly induced free radicals. model proposed is that absorption of radiation energy may lead to a localized heating of small regions; this may allow radical reactions to take place at a rate characteristic of a much higher temperature than the average temperature of the sample. Evidence for this model includes the fact that there are differences in the spectra from irradiated glycine and valine after very high doses and lower doses of radiation energy1; the effects of different linear energy transfer radiations2; and the changes in the glycine spectra as functions of dose and time3. The validity of such a model depends on the assumption that the energy deposited by the radiation cannot diffuse by a conduction process, as only then can a local "hot spot" be created. A theoretical examination of this problem is hampered, however, by a lack of knowledge of the processes involved; in particular, no measurements have been made, as far as is known, on thermal conductivities. As a first step, an investigation was therefore made of the thermal conductivity of a single crystal of glycine.

The method adopted was the thermal-comparator technique (ref. 4, Fig. 7) developed by Powell. A 'Chromel' probe block was used, and a 100 g weight, which could be fixed on the top, ensured a constant pressure by the comparator on the system. The potential difference from the thermocouple was measured with a microstep potentiometer (Cambridge Instrument Co., Ltd.). Three reference materials of known conductivity (0.0037, 0.010 and 0.018 Joules cm/cm²sec °C) were used to

calibrate the comparator.

The single crystals of glycine were grown by slow evaporation from aqueous solution. They are monoclinic in form, with an elongation along the c-axis. Surfaces parallel to the a-c plane had the largest dimensions (approximately $1 \text{ cm} \times 0.5 \text{ cm}$) and their thickness was 2-3 mm. Most of the measurements were made with the probe resting on the a-c plane surface, although a few were tried on the b-c plane surface. None were possible on the a-b plane surface as the dimensions were too small to support the probe. No significant difference was found between the two surfaces investigated.

Measurements were made with the comparator at 60° C and 82° C, the temperatures being taken with a mercury-in-glass thermometer monitoring the oven used to heat the comparator. Results are plotted in Fig. 1, where the circled points refer to the glycine. Comparator readings have standard deviations of about ±2 per cent, and to this degree of accuracy it can be seen that there is no difference in the thermal conductivity of glycine at the two temperatures used. It is concluded that the thermal conductivity of glycine is 0.013 Joules cm/cm² see °C.

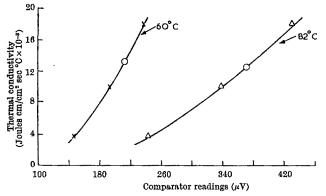

Fig. 1. Relationship between thermal conductivity and comparator readings. Circles denote glycine readings.

The implication of such a low value is that conduction in this material is predominantly by means of the lattice. (It is reasonable to assume that other aliphatic amino-acids will have comparable thermal conductivities.) Thus the absorbed energy cannot readily be evenly distributed throughout the whole sample, but tends to remain close to the point of deposition. This results in the local heating and radical reactions postulated to account for the electron spin resonance data.

MOLECULAR STRUCTURE

Bonding Radii of 80S Ribosomes

THERE are now clear descriptions of the packing of ribosomes from two different nucleated organisms into two different crystal forms. One form, the chromatoid bodies of *Entamoeba invadens*, is a hexagonal array of helices¹. The other form, found in mitotic cells of chilled chick embryos, consists of tightly packed layers of plane lattices². At first sight there is no apparent relation between the packing of ribosomes within these two forms. We will show, however, that there is a way of looking at the bonds which these ribosomes form which closely relates one packing scheme to the other.

Byers² has shown that the ribosome crystals found in chick embryos belong to the space group P422. His micrographs show that the ribosomes are not in the general positions of this space group, but rather in very special ones. Fig. 1a gives a view of this packing perpendicular to the four-fold axes. Nothing in the symmetry of the space group demands that the distances marked d_1 and d_2 in this figure should be equal. Yet they are. By using either this property, or the equivalent one that ribosomes fall along mutually perpendicular families of lines, one can find, by algebraic geometry, that the special positions occupied by ribosomes in this particular lattice are described by the co-ordinates x=3/10a and y=1/10a, where a is the length of the square face of the unit cell, 540 Å. As a consequence α , the angle between centres of the ribosomes and the cell edge, is arc $\tan(y/x) = 1/3$ or 18.4°, as Byers has observed.

Fig. 1b shows a section of the same packing parallel to the four-fold axes and through the ribosomes marked I in Fig. 1a. Again note the symmetry of the space group does not demand that the distances marked d_3 and d_4 should be equal. Yet they are, and so we deduce that the special value of the z co-ordinate is $z=\frac{1}{4}c$, where c, the

height of the unit cell, is 700 Å.

Given these co-ordinates of any ribosome in the crystal, it is easy to compute the centre-to-centre distances between nearest neighbours. In the planes (Fig. 1a), these neighbours are 240 Å apart, as Byers has noted², while botween planes (Fig. 1b) nearest neighbours are 366 Å apart, and situated along lines making an angle β of $17\cdot1^{\circ}$ (that is, are $\tan=y/z$) with the long edge of the cell. The ratio of these two closest approaches is $1\cdot5$.

When we use these numbers to define the lengths and directions of what we call the "effective bonding radii" of these ribosomes, the resulting pattern is pictured in Fig. 2a. We may describe its construction as follows. (1) A bonding site of radius 120 Å occurs along the equator of three meridians: 0° , 90° , 180° . Call these s_1 , s_2 , s_3 .

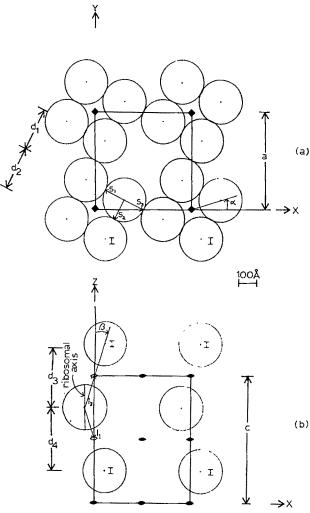

Fig. 1. Crystal packing of ribosomes within chilled chick embryos. Data from Byers*. a, Section perpendicular to four-fold axis; b, section parallel to four-fold axis.

(2) Along the fourth such meridian, 270°, there is no bonding site. Moreover, the electron micrographs give an indication of "clefts" here (see ref. 2). (3) Along meridian 90°, and at angles of $17 \cdot 1^{\circ}$ to each pole, there are bonding sites of radius 180 Å. Call these l_1 and l_2 .

The rules governing ribosome packing within the crystal form of chick embryos are therefore: (a) s_1 and s_2 bond with each other (these are the "tetramer" bonds); (b) s_3 bonds with s_3 (the "dimer" bonds). (Note that $|s_1| = |s_2| = |s_3|$.) (c) l_1 bonds with l_2 , and l_2 bonds with l_2 (the bonds holding successive planes of ribosomes together). Ribosomes of the shape described joined by these rules will form the observed crystal.

We have applied the same procedure to the helical packing found in chromatoid bodies¹. In 1966 when this packing was described it was noted that two types of bonds between ribosomes were probably effective here. One bond joined every other ribosome along the helix of twelve nodes in five turns (that is, nodes n and n+2, see Fig. 3c). This resulted in two sets of chains, each having six nodes in one turn. The other bond was proposed to join the chains to each other in dimers (node n to n+1). The radius proposed for the centres of ribosomes was 150 Å.

Using this radius, and the helical parameters found for this packing (rotation of 150° , translation of 75 Å), we calculate that the distance between nearest ribosones (n and n+2) is 212 Å, while that between next nearest (n and n+1) is 300 Å. The ratio of these approaches is 1.4. In the plane formed by any three successive ribosomes (say n-1, n, and n+1), their centres form an isosceles triangle with apex at ribosome n (see Fig. 3n). In this plane, the angle between the long bonds $(l_1 \text{ and } l_2)$ formed by this ribosome is 42° .

There are short bonds $(s_1 \text{ and } s_2)$ between ribosomes in this helical form. These lie in the plane formed by centres of ribosomes n-2, n, and n+2 (see Fig. 3b). Here they subtend an angle at the ribosome n of 132°. The angle between the planes of the long bonds and short bonds is 86°. Thus this form can be given a description similar in many ways to that given for the chick ribosomes but with different angles for the amoeba ribosomes. But in the amoebal ribosome, the mid-portion of meridian 90° is now occupied by the two long bonds, leaving no room for

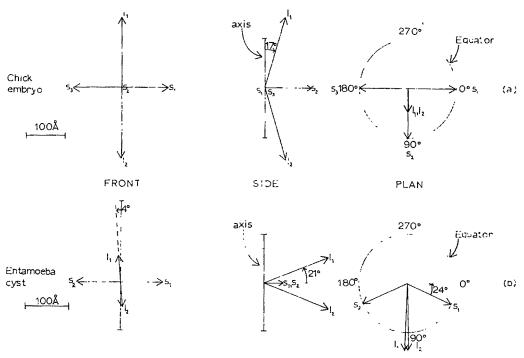

Fig. 2. Bonding radii of ribosomes from (a) chick embryos and (b) cysts of Entamoeba invadens.

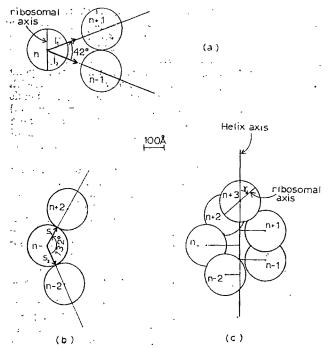

Fig. 3. Crystal packing of ribosomes within chromatoid bodies of *Entamoeba invadens*. Data from Morgan and Uzman¹. a, Plane through centres of ribosomes n-1, n, n+1; b, plane through centres of ribosomes n-2, n, n+2; c, projection onto a plane through ribosome n and the helix axis.

a third short bond such as the chick ribosome possesses. Perhaps as a consequence of this arrangement, amoebal ribosomes only have two short bonds. Again, the packing is formed by a similar rule which may be condensed to "long bonds to long" and "short bonds to short". The bonding radii of amoebal ribosomes are shown in Fig. 2b. In the helix, the ribosomal axis is inclined to the helix axis at an angle γ of 49° (see Fig. 3c).

Thus to deform an amoebal ribosome into a chick ribosome we must first straighten out the bend between s_1 and s_2 , so that they are diametrically opposed, and then increase the angle between l_1 and l_2 from 42° to 146°, thus disclosing a third short bond on the equator of meridian 90°.

So far our description has simply rephrased the geometry which relates the centres of electron-dense stain seen in electron micrographs of sections through ribosome crystals to each other. What physical structures underlie these vectors? Indeed, do parts of the ribosomal RNA or protein extend from the centre of the ribosome to the full length of these bonding radii? These questions, involving resolution beyond that given by the micrographs, cannot be answered by electron microscopy. Nor can these micrographs give an unequivocal answer to a third question: what is the relation between these bonding radii and the subdivision which divides all ribosomes into two-thirds and a third?

One possible way in which this subdivision could occur is suggested to us by the number and lengths of the bonding radii of the chick ribosomes: assume that mass is distributed along these radii in proportion to their length. Then l_1 , s_2 and l_2 will collect a mass of 4, while the remaining bonds s_1 and s_3 will collect a mass of 2. Thus l_1 , s_2 and l_2 will constitute two-thirds of the total mass, and could represent the larger (60S) sub-unit, while s1 and s3 will constitute one-third and could represent the 40S sub-unit. Even though a third short bond is not seen in the amoebal ribosome, a similar mass distribution could easily occur.

Another way in which these ribosomes could be subdivided is suggested by the electron micrography of extracted particles, either negatively stained3,4

shadowed⁵. From such images, one gets the impressions (1) that the larger sub-unit should include bonds s_1 and s_2 , as shown in Fig. 2b or Fig. 3b for the amoebal ribosomes, and (2) that the smaller sub-unit should include only those portions of bonds l_1 and l_2 which extend beyond a distance from the centre of the ribosome approximately equal to s_1 or s_2 . We can draw an envelope around s_1 and s_2 which will include twice the volume (and therefore twice the mass) of an envelope drawn around only the outer portions of l_1 and l_2 , but the manner in which the envelope is drawn is not specified by the crystallographic data in any exact way. The resultant shape is exactly that shown by Shelton and Kuff⁴ in their Plate I, c, d and f.

We can relate this second conception of ribosomal structure to two other pieces of evidence concerning ribosomes from *E. coli*. Langridge and Holmes⁶ observed that gels of 50S particles from this organism gave spacings corresponding to orders of 212 A. We would attribute this spacing to s_1 - s_1 bonding of the large sub-unit. Huxley and Zubay³ observed (see their Plate VIII, b, bottom row) dimers of 70S particles, in which we measure the centreto-centre spacing between the larger sub-units to be close to 300 Å. This we interpret as l_1-l_1 bonding. correspondence between these distances and those observed for the amoebal ribosomes is striking.

Our analysis of the two known crystalline forms of ribosomes shows that both ribosomes have a pair of long contacts or bonds in a plane very nearly perpendicular to the plane of a pair of short bonds, that the ratios of these bond lengths is very close to 1.5 and that within their planes each bond occurs at a defined angle.

We thank Donna Myer and JoAnn Lyerla for assistance.

MICROBIOLOGY

Sorption of Water Vapour and Nitrogen Gas by Bacterial Spores

As a result of their high refractility and their resistance to stains and to lethal agents such as heat and chemicals, it has long been thought that bacterial spores are relatively dry and impermeable. There is conflicting evidence, however, about the degree of desiccation and impermeability which may exist. Refractive index measurements on spores in aqueous suspensions indicate very low water contents1, and the surface area of lyophilized spores available to adsorption of nitrogen gas is so small that little or no internal porosity can be postulated2. On the other hand, it has been demonstrated that spores have a significant affinity for water3. In aqueous media it is known that germinants enter spores rapidly and evidence has been presented for considerable porosity and a water content as high as 75 per cent of the dry weight4. effort to account for these discrepancies, we have employed standard gas adsorption techniques to measure water vapour sorption of intact and crushed spores and the nitrogen gas adsorption of spores which were dried in various ways. The results confirm the hydrophilic nature of spores and indicate that a considerable fraction of the volume occupied by water in wet spores can be preserved

in the dry state by employing dehydration methods which minimize the collapse of hydrophilic, macromolecular structures.

Clean refractile Bacillus subtilis var. niger spores with a viability of 70–100 per cent were obtained by centrifugation in density gradients of sodium bromide solutions followed by washing in water until the washings were free of bromide. Spores were dried by freeze-drying and by a solvent replacement procedure. The latter was carried out by washing the spores six times in absolute ethanol in centrifuge tubes which were provided with airtight caps. The alcohol was replaced by at least four washes of dry pentane. In the final alcohol wash and in all the pentane washes, the removal of supernatant and the addition of fresh solvent were carried out in a dry nitrogen atmosphere. The pentane was finally removed from the spores by evaporation at its boiling point (36° C). The viability of the spores was not significantly affected by the solvent replacement process.

Crushed spores were prepared by shaking an absolute ethanol suspension of clean spores with 0.2 mm diameter glass beads for 4 min at 4,000 r.p.m. in an MSK Braun homogenizer (Bronwill Scientific, Inc.). After removing the glass beads on a coarse frit and washing the suspension with ethanol, the crushed spores were spun down and dried directly from alcohol for water vapour sorption studies. For nitrogen adsorption, the alcohol in the suspension was replaced with pentane and evaporated as described. Less than 6 per cent of the dry weight of the original spores was lost during the entire process. Electron micrographs of crushed spores which were dried directly from alcohol suspension and shadowed with platinum showed recognizable spores with extensively ruptured coats and some spore fragments of unidentified origin.

Water vapour sorption was determined gravimetrically on well dispersed, 20-25 mg samples of spores using a quartz spring balance (Microchemical Specialities Co.) with a sensitivity of 1 mm/mg. The experiments were carried out in an air-conditioned room at 23° ± 2° C. After introducing the sample, the apparatus was pumped down to a residual gas pressure of 0.05 mercury before introducing water vapour. Equilibrium vapour pressures were measured to ± 0.05 mm mercury or less with a mercury manometer. During adsorption, water vapour was admitted to the system in doses, by momentarily opening a stopcock leading to a storage bulb of liquid water. During desorption, water was removed in successive stages by freezing in a cold trap. The time required to reach a constant weight at each pressure was longer at low than at high pressures, but in no case was it more than 2 h. After two or more complete adsorptiondesorption cycles (reproducible to about ± 8 per cent or better at all points), the sample was heated to constant weight at about 110° C. This weight was used to compute the water uptake for the sorption curves plotted in Fig. 1. The heating process causes a weight loss of about 4 per cent compared with the weight at room temperature and zero partial pressure of water. After rehydrating the heated samples, however, it was found that the sorption curves obtained before heating could be reproduced. The weight loss is thus caused by a small amount of tightly bound water.

Nitrogen adsorption measurements were made on spore samples $(0\cdot2-1\cdot0$ g) by the American Instrument Company. Spores were degassed by evacuation at room temperature until a pressure of less than $0\cdot05\mu$ mercury was maintained. The surface area ascribed to a monomolecular layer of nitrogen on the sample was calculated by the Brunauer, Emmett and Teller (B.E.T.) procedure using 16·2 Ų as the area of the adsorbed nitrogen molecule.

The water sorption of both intact and crushed spores (Fig. 1) is similar to that of natural polymers such as polysaccharides and proteins; the adsorption isotherms almost match those for dewaxed, washed wool⁶. Some of

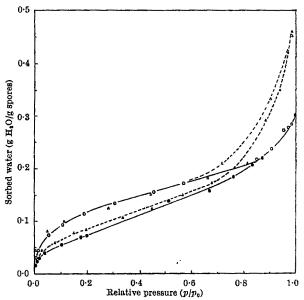

Fig. 1. Water sorption of Bacillus subtilis spores as a function of relative pressure of water vapour (relative humidity). Filled points represent adsorption, open points represent desorption. ——, Freeze dried spores, ---, crushed spores.

the interpretations derived from the extensive studies of these simpler materials seem appropriate here7. The sigmoid shape of the curves is typical of solids which have a high affinity for water and can swell as water uptake progresses. The steep slope of the water uptake curves at low relative humidities (p/p_0) may be attributed to strong binding by specific sites accompanied by the evolution of heat. At intermediate relative humidities, water is held less energetically and, subsequently, the adsorbent swells in the process of forming a solid solution. The ultimate amount of water taken up in this latter process seems to be limited by the swelling constraint imposed by the molecular structure of the adsorbent and by the capillarity of the sample. Hysteresis is also typical of swelling adsorbents. It is not caused by failure to reach a stable water uptake but rather by different macromolecular constraints in the adsorbent, depending on whether a particular water content is approached by desorption or adsorption8,9.

A striking feature of the curves for crushed spores is that they are very similar to those for the intact spores at low and intermediate relative humidities in spite of the extensive exposure of internal structures. This indicates that the water uptake must be attributed to sorption by structures in the bulk of the spore and cannot be effected merely by the external surface. It also shows that no significant number of primary water-binding sites have been made available by rupturing the spore coat. This is an argument against the existence of water permeability barriers which could maintain an anhydrous spore core. Crushed spores show a slightly narrower hysteresis and an increased water uptake at higher humidities compared with intact spores; this signifies a decreased constraint on swelling. Whether or not the core substance is responsible for most of this swelling as some workers have suggested10 cannot be conclusively decided until water sorption data are available on isolated parts of the spore anatomy.

Typical surface areas of the various spore preparations as determined from nitrogen adsorption measurements are summarized in Fig. 2. The surface area of freezedried spores (7 m²/g) is nearly the same as the external geometrical area (6 m²/g) calculated from the average dry weight of each spore and the spore dimensions obtained from electron micrographs assuming an ellipsoidal shape. This is in agreement with the results which Berlin, Curran and Pallansch² obtained for a variety of freeze-dried spores.

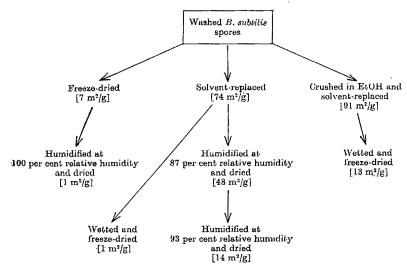

Fig. 2. A summary of the drying procedures for *Bacillus subtilis* spores and the corresponding surface areas (in m²/g) as calculated from the adsorption of nitrogen at -195°C using the B.E.T. procedure. Humidification was accomplished in the sequences indicated by the arrows, by passing air at the indicated relative humidity through the spore samples and then drying by evacuation or by wetting with liquid water and freeze-drying.

If the drying is carried out by solvent replacement, however, an approximately ten-fold increase in area is available. This additional area is most readily accounted for by the presence of accessible surface area in pores existing in the bulk of the spore. It is not the result of extraction of substituents by the organic solvents because the expanded structure can be collapsed again by contact with water. Thus the area lost on equilibration of the expanded spores with humidified air or liquid water followed by drying by evacuation or freeze drying, respectively, increases in proportion to the degree of humidification (Fig. 2). Areas less than that calculated for the geometrical surface area of the spores (< 6 m²/g) can occur as a result of agglutination. The areas of crushed spores parallel those for similarly dried intact spores; the somewhat larger value for crushed spores is consistent with their smaller particle size.

The wide variation in nitrogen surface area with different methods of sample preparation is well known, especially in the literature on cellulose¹¹, and the interpretations offered there seem applicable here. On this basis we suggest that the following model is consistent with the data on bacterial spores. In the water-wet state, the spore (or at least the part of the spore external to the core and possibly the cortex) is swollen and a water-filled porous structure exists in accordance with the findings of Black and Gerhardt4. On drying in air or even freezedrying, this porous structure collapses completely. Many of the hydrogen-bonding sites on the macromolecular constituents of the spore, initially interacting with water, are likely to be satisfied by interaction between adjacent chains as the water moves out. These intermolecular spaces are closed during the drying process until, in the completely dry state, non-polar molecules, even those as small in size as nitrogen, are unable to penetrate the exterior surface. Voids in the interior of the dry spore appear highly unlikely, but they cannot be ruled out on the basis of our data. If the water is removed by the solvent-replacement procedure, however, considerable porosity is retained. That this porosity represents only a part of the porosity existing in the water-wet state is indicated by the fact that the area available for water sorption computed from the water adsorption isotherm by the B.E.T. procedure amounts to 240 m²/g (taking 10.5 Å² as the area of a water molecule). We cannot at present specify which of the several steps in the solvent-replacement process is responsible for this shrinkage. In the case of cellulose, the surface area losses seem to occur chiefly

during the final evaporation and are reduced as the surface tension of the evaporating hydrocarbon liquid is lowered11.

A more quantitative discussion of such questions as the pore size distribution of spores dried by solvent-replacement and of a correlation of these pore sizes with those found in the water-wet state must await an exploration of conditions for the preparation of spores with maximal surface area. A reconciliation of the results of optical methods of determining water content¹ with the higher values obtained by other methods here and elsewhere3,4 awaits the availability of optical and water content data on the individual anatomical regions of the spore. The mechanism of the striking loss of surface area occurring during the freeze-drying process, both with spores and with cellulose¹¹, seems worth investigating in view of the widespread use of this method to dehydrate biological and other hydrophilic materials with the intention of preserving structure.

We thank Mr D. Spiner for supplying spore samples.

Novel Approach to studying Relationships between Mycoplasmas and Tissue Culture Cells

Most continuous cultures of tissue cells are contaminated with mycoplasmas1, which can be detected by staining2, immunofluorescence3, isolation3 or biochemical studies4. Furthermore, the interaction of mycoplasma organisms with HeLa cells and other types of mammalian cells has been studied with the electron microscope^{5,6}. Electron microscopy, in particular, shows that there is an intimate relationship between mycoplasmas and infected cells, which might explain why it is so difficult to eliminate these organisms from tissue culture cell lines and strains.

Del Giudice and Pavia, used a completely different macroscopic technique to study the relationship between Mycoplasma pneumoniae and erythrocytes. They observed that guinea-pig erythrocytes poured over M. pneumoniae colonies on agar medium adsorbed to the colonies after a short period of incubation at 37° C. This phenomenon of haemadsorption has since been observed with a number of other mycoplasma species and with erythrocytes from other mammalian and avian species. Furthermore, we have observed adsorption of bovine and human spermatozoa to colonies of several mycoplasma species and to sheets of M. gallisepticum organisms attached to plastic Petri dishes. It was logical to use this technique

to study the association between mycoplasmas and tissue culture cells. Thus we have not infected cells in culture, but we have observed the adsorption of tissue culture cells in suspension to mycoplasma colonies and sheets.

Details of the mycoplasma growth medium have been presented previously^{8,10}. We used mycoplasma colonies on pH 6.5 agar medium, and sheets of mycoplasma organisms adherent to the base of plastic Petri dishes11. These mycoplasma sheets were washed three times with 5 ml. of Difco PPLO broth before use. The tissue culture cells used in these experiments were M-HeLa12. They were grown as monolayers in Roux bottles in Eagle's medium containing 10 per cent ox serum. The cells were collected by treatment with 0.05 per cent versene at 37° C for 10 min and were resuspended in a small amount of the cell culture medium. Immediately before use the cells were centrifuged at 900g for 10 min, washed once with 0·1 molar phosphate buffered saline (PBS), pH 7·2, and resuspended in PBS at a concentration of about 106 cells/ml. Then 1.0 ml. of the cell suspension was poured over the mycoplasma colonies on agar or over the mycoplasma sheets adherent to plastic and these preparations were incubated at 37° C for 15 min. The colonies and sheets were then examined under a plate microscope for adsorption of the HeLa cells and again after excess cells had been removed by washing with PBS.

We chose to study M. pneumoniae and M. gallisepticum because haemadsorption and spermadsorption had been demonstrated previously⁷⁻⁹, and M. hominis because this mycoplasma is a frequent tissue culture contaminant. Fig. 1 shows the appearance of a colony of M. gallisepticum before and after the addition of HeLa cells; the surface of the colony is covered by adherent cells. Table 1 shows results obtained when HeLa cells were added to the three different mycoplasma species mentioned compared with those obtained in haemadsorption and spermadsorption tests. Colonies and sheets of M. gallisepticum and M. pneumoniae which extensively adsorbed both erythrocytes and spermatozoa also adsorbed HeLa cells extensively. Moreover, colonies and sheets of M. hominis adsorbed HeLa cells extensively in spite of the fact that they adsorbed neither erythrocytes nor spermatozoa. This is of particular interest in relation to the frequent finding of this mycoplasma as a contaminant of tissue cultures. In addition, the cells could not be dislodged from any of the colonies or sheets by normal washing procedures.

The simplicity of this test system is valuable for two reasons. First, it is possible to examine the adsorption of cells derived from various avian and mammalian tissues to different mycoplasmas, and so obtain further information on mycoplasma host specificity and tissue affinity. Second, the system affords an opportunity to determine the effect on adsorption of treating both mycoplasma and cell with various reagents and so define the nature of possible receptors. Gesner and Thomas¹³ have indicated that sialic acid receptors on erythrocytes are involved in the agglutination of such cells by M. gallisepticum. In our experiments, the affinity noted between M. hominis and HeLa cells was in contrast to the lack of affinity previously observed between M. hominis and erythrocytes or spermatozoa. This suggested that some unusual sort of receptor mechanism was involved in the case of the HeLa cells. We therefore treated HeLa cells by incubating them

for 1 h at 37° C with neuraminidase, and then tested for adsorption. Neuraminidase treatment of cells inhibited their adsorption to sheets of M. hominis organisms, indicating that neuraminic acid receptors on the HeLa cells were involved in this reaction. Such a bond between HeLa cell and mycoplasma organism would be one possible explanation for the difficulty encountered in climinating the organism from cells in continuous culture.

We thank E. J. Stott for supplying us with HeLa cells, and Mrs S. Beveridge for technical assistance.

Ageing Effect on Phage Particles leading to an Increase in Burst Size

In constant conditions, the burst size of a particular bacteriophage is a characteristic of that bacteriophage. We have found aged P4/2 phage particles yield larger

burst sizes than young phage particles.

The bacteriophage P4/2 was isolated from Salmonella potsdam (NCTC 3206) and propagated on another strain of S. potsdam, SP2, which seems to be non-lysogenic1. Phage lysates were stored in a refrigerator, and at periodic intervals one-step growth experiments were performed in which the multiplicities of infection were between 0.01 and 0·1. A steady increase in the average burst size was found with an initial low value of 34 from cells infected with fresh phage particles to a high value of 786 for cells infected with phage particles which were I month old. The burst sizes from cells infected with phage stored for times longer than 1 month were approximately the same as those obtained with cells infected with month old phage. The rate of adsorption, determined by measure of both unadsorbed phage and of infective centres, was found to be independent of the age of the infecting phage particles. Neither the rate of adsorption nor the burst size itself was affected by variations in the multiplicity of infection. The burst sizes produced by phage lysates kept at both higher and lower temperatures were like those yielded by phage kept for the same time in a refrigerator even though there was a drop in the plaque forming titre of lysates kept at higher temperatures.

In a series of single burst experiments, the proportion of infected cells which gave rise to small numbers of phage progeny was high when young phage particles were used for infection but low when old phage particles were used. The proportion of cells infected with aged phage particles, which yielded large bursts, was also significantly higher. These results support those obtained in the one-step growth experiments but give the added information that the differences in the average burst size are directly related to the size of the burst from individual cells rather than to differences in the proportion of cells which

release phage progeny.

A series of premature lysis experiments was performed with lysates which gave bursts of different sizes. The length of the eclipse phase was found to be shortened as the burst size increased although the latent period itself remained constant at 40 min. The shortest eclipse phase was 20 min for a burst of 700, the longest was 35 min for a burst of 34. Thus the length of the eclipse phase was

inversely proportional to the size of the burst.

If there is the same relationship between phage DNA and the appearance of mature, intracellular phage with this phage and its host as there is with T2 infected cells of E. coli, a delay in the appearance of intracellular phage would mean a delay in the synthesis of DNA². Attempts to test this directly have so far failed because, at the low multiplicities of infection necessary to prevent lysogenization, the net DNA synthesis was not representative of phage infected cells. We cannot therefore determine whether the delay which results in initial, small average burst sizes attributed to one or more phage regulated functions is associated with a delay in the onset of phage DNA synthesis or in the maturation process with a consequently larger DNA vegetative pool.

This investigation was carried out under contract from the US Office of Naval Research.

Distribution of the Soluble Dehydrogenases and Diaphorases of Brucei Subgroup of Trypanosomes in Starch-gel Electropherograms

Antigenic variation in the brucei subgroup of trypanosomes considerably limits the development of a suitable anti-trypanosomal vaccine, and this limitation is likely to continue until we have more knowledge of the nature of antigenic variation. Until then, however, more information about the nature of trypanosome antigens would be useful.

Some of the variable antigens are soluble proteins and the variation seems to be associated with changes in their immunological specificity¹⁻³. We have separated soluble trypanosome proteins into at least twenty-nine components by starch-gel electrophoresis, and in an attempt to characterize these components we tested for glucose-6-phosphate dehydrogenase which was known to be present. This was found in the region occupied by the major 4S variable antigens of Williamson and Brown³ (bands 1-7 in Fig. 1). This suggested that the antigens might be dehydrogenases, and so we made a survey of some of the dehydrogenases and diaphorases of carbo-hydrate metabolism. We present here the results of the distribution of these enzymes in starch-gel electropherograms and discuss their possible role in metabolism.

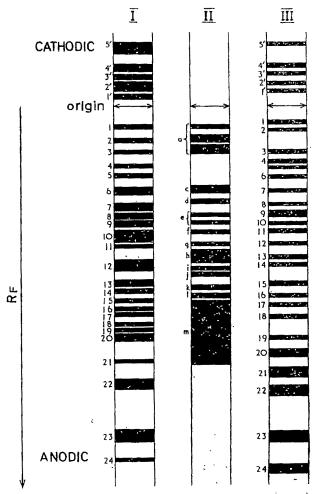

Fig. 1. Starch-gel electropherogram of the rat serum and soluble trypanosome proteins. I, EATRO-691; II, normal rat serum; III, T. rhodesiense, SS 518. The figure is a combined scale drawing from different preparations run at different times. The rat serum notation is that of Beaton et al. 19. 0-05 molar glycine/sodium hydroxide buffer, pH 8-9, gel; 0-05 molar borate buffer, pH 8-58, electrode chambers; 8 V/cm, 2-5 h. Proteins stained in 1 per cent amido black 10B in methanol/water/acetic acid (50/50/10, v/v):

^{*} Nutter, R. L., and Sinsheimer, R. L., Virology, 7, 276 (1959).

A brucei subgroup isolate EATRO-691 and T. rhodesiense isolate, SS 518, were used for this study and prepared soluble proteins from these organisms as previously described. The protein solution was loaded onto strips of filter paper which were then inserted into a starch gel previously prepared in glycine-sodium hydroxide buffer. An uninfected rat serum control was run at the same time and bromphenol blue was applied as a tracking dye to a hole on one side of the gel. Horizontal zone electrophoresis was carried out in the cold room at 2°-4° C, for 2·5 h at a volt gradient of 8 V/cm. The gel was then sliced horizontally, one slice stained for proteins and the remainder for enzymes.

The enzyme test system for dehydrogenases and diaphorases was essentially that of Fildes and Parr⁷ and consisted of an "overlay" made up of agar (45 mg) in

0.3 molar tris hydrochloric acid buffer (pH 8.0, 1.6 ml.), to which was added 0.1 molar magnesium chloride (1.6 ml.) and water (1.3 ml.) mixed at 45° C with the tetrazolium salt 'Nitro BT" or 'MTT" (0.9 mg), phenazine metho sulphate (PMS, 0.2 mg), NAD or NADP (0.4 mg), EDTA (disodium salt, 12 mg), and the particular test substrate at a final concentration of 1.5–2.5 mmolar. In the case of diaphorases, NADH or NADPH (0.5 mg) were the substrates and NAD, NADP and PMS were omitted. The enzyme was located as a bright blue zone. The protein and enzyme bands were correlated by comparing their R_{FS} (ref. 8).

Fig. 1 shows a combined scale drawing of an electropherogram of several different preparations run at different times. Although not all components appeared in each preparation on each occasion, the bands from dif-

ferent preparations could be reproduced to within one R_F value. Some of the protein bands had the same mobility as the rat serum proteins, but two observations suggested that these were not contaminants from the rat serum. First, the method of preparation9 gives trypanosomes which are about 99 per cent pure and the concentration of the serum proteins is so low that they are unlikely to be detected by the protein stain. Second, in the enzyme histochemical localization, the mobility of the trypanosome enzymes does not correspond with that of the serum enzymes.

NADH and NADPH diaphorases and isocitrate (EATRO-691 only), ethyl alcohol, glucose-6-phosphate (G-6-P), 6-phosphogluconate (6-P-G), glutamate, 3-phosphoglyceraldehyde, α-glycerol-phosphate, lactate, lipoate, malate and succinate dehydrogenases were tested for and, apart from lipoate, they were all detected. distribution of these enzymes among the bands is shown in Table 1. Some of the enzymes have mobilities falling between the stained bands. These could be highly active enzymes in very low concentration which are not therefore stained by amido black 10B or, more likely, the assigned mobility may result from an error in measurement. In general, the enzyme pattern was the same for both isolates. but in some cases the number of bands differed. Usually, the mobility of the trypanosome enzymes differed from the rat serum enzymes, but when they coincided the trypanosome ones were assumed to be contaminants from the rat serum.

All the enzymes seemed to be isoenzymes except α-glycerol-phosphate and lactate dehydrogenases in EATRO-691 and 3-phosphoglyceraldehyde in both trypanosome isolates. They all had a low specificity for NAD and NADP with the exception of glutamate, ethyl alcohol and succinate dehydrogenases which were specific for NAD. Although the enzymes reacted with both NAD and NADP, not all the bands did so. Several of the bands of various isoenzymes seemed to have the same mobility, but it is not clear whether one band is an enzyme with more than one activity or whether the band is composite. With some of the enzymes-malate dehydrogenases, for example—the bands reacted with NAD in both rat serum and trypanosomes. With NADP, however, except for one band in the rat, only the trypanosome enzyme reacted.

All glycolytic dehydrogenases have been found in this study, which can be taken as a further confirmation of the accepted10 classical Embden-Meyerhof pathway of glucose catabolism. Work on the distribution of carbon-14 on labelled metabolites in these organisms suggested that the Krebs cycle is inactive^{11,12}. Both isocitrate and succinate dehydrogenases have been found and confirmed cytochemically (our unpublished results). Shaw et al.12 did not detect the formation of 2-oxoglutarate from carbon-14 glucose, and Ryleys found that the blood forms did not utilize 2-oxoglutarate so it can only be concluded that there is a by-pass in the pathway from isocitrate to succinate. It is, however, difficult to explain the absence of 2-oxoglutarate (usually a product of glutamate transferase) when the presence of glutamate dehydrogenase has been confirmed.

Distribution of Experimentally Induced Scrapie Lesions in the Brain

Lesions of scrapie are confined to the central nervous system. Differences in the distribution of these lesions have been described for the two strains of scrapie agent used in goats1 and for the lesions which arise as a result of injecting mice with boiled and unboiled material2. We have also collected unpublished data showing wide variation in the distribution of lesions which result from using different strains of the agent in mice or by inoculating different genotypes of mice with the same agent.

In order to estimate the concentration of scrapic agent in various tissues of four strains of mice, the tissues were removed from animals which had been killed at intervals between the time of challenge with the ME7 strain of agent and development of the clinical disease. One of the four mouse strains, C57BL, also served as the test strain in bioassay of the scrapie titre. As a result of the routine use of a system which we have developed3 for measuring the degree and spatial distribution of scrapie lesions in the brain, it has been possible to examine a number of potential sources of variation in these lesions, such as sex of the test animal, titre of scrapie in the inoculum, strain differences between donor and host, and the finer specificities associated with the particular donor tissue which forms an integral part of the inoculum. So far we have data for scrapic agent in the brain and in the spleen.

All the donors which we used were females of the strains C57BL, SM, LM and VM; the latter differed notably from the others in the alleles of the gene sinc, which controls ME7-scrapie incubation period4. Rigorous aseptic precautions were used when tissues were removed, to prevent cross contamination between different organs. For injection, the tissues were ground and made up in a saline suspension to give an overall concentration of 10-2. This was then spun at 300g for 10 min and 0.02 ml. of the supernatant was administered intracerebrally into mice. An elaborate bioassay design involving 273 C57BL mice was used to minimize random or fluctuating sources of error, both at the time of preparation of the inoculum and during measurement of the incubation period. The brains were removed for histological examination at the same stage in the progression of the clinical disease. The degree of vacuolation in the various regions of the brain was scored on a scale ranging from 0 (no vacuolation) to 5 (vacuoles confluent throughout the defined brain location)3.

As seen in Table 1, the degree and distribution of lesions are unaffected by sex. When, however, the degree and distribution of lesions from each tissue source are compared, either within the same sex or on an overall basis as in Fig. 1 and Table 1 (col. 3), differences can be seen. Thus the lesions are more advanced in the anterior midline cerebral cortex, hippocampus and paraterminal body and less advanced in the cerebellum when scrapie brain is used as the inoculum than when scrapie spleen is used as the source. These differences are present in tissues taken from donors in all stages of the disease (Table 1, columns 4-9). It has been established that the scrapie titre in spleen is uniformly high in all strains at 08 07 08 08 04 07

these stages of incubation; the stages do, however, represent an increasing titre in the brain, over a 10,000 to 100,000-fold range, as incubation advances. Final levels in the brain and spleen are about the same (ref. 5 and our unpublished results). The general pattern of differences shown in Fig. 1 is independent of the presence or absence of isogeny between donor and host (Table 1, cols. 10-13).

These findings are the unexpected results of an experiment which was designed with an entirely different aim in view and we had no initial intention of analysing the lesion distributions in the assay animals. The results seem to be entirely consistent throughout the data. Other experiments are now needed to discriminate between two chief possibilities, either that the scrapie agent may have been modified in the different donor tissues, or the described effect stems from accompanying organ-specific constituents which could involve some immunological process.

PATHOLOGY

Induction of a Neurological Disorder by Cycasin in Mice

SINCE an unusually high incidence of amyotrophic lateral sclerosis, a neurological disease, was found on the island of Guam by Kurland and Mulder¹, the search for the cause of the disease has been focused on Cycas circinalis, which the Guamanians have long utilized as a source of food starch. Ingestion of cycad plant material in the tropics and subtropics where eyeads are indigenous has been reported to cause posterior weakness and ataxia, with a characteristic "goose-stepping" gait in cattle?. Numerous feeding experiments have been conducted to evaluate the disputed conditions in which cycad paralysis

occurs, but one cannot be sure that the test animals were not exposed to other risks which could produce locomotor difficulties, except for the experiments which were carried out in controlled conditions. Recently, Anderson and Hall³ reported that cattle which had been fed fresh cycad leaves showed a slight lack of co-ordination in the hindquarters which resulted in a swaying gait. None of the glycosides which are contained in cycads, however, has been shown to be responsible for producing such neurological disorders.

Laqueur et al.4.5 found that cycad meal and cycasin, a methylazoxymethanol glycoside which is contained in cycads, produce a carcinogenic effect in rats. The same effect of cycad material in guinea-pigs and mice was reported by Spatz⁶ and O'gara et al. 7, respectively. The neurological disorder was not, however, observed in these

In the course of the experiment to investigate the carcinogenicity of cycasin, we accidentally found that mice which were treated with cycasin showed a high incidence of neurological disorder. Mice used in this experiment were supplied by the National Institute of Genetics. Sixty newborn mice, less than 24 h old, from the eleven mothers of the inbred strain C57BL/6 received a single injection of 0.5 mg of cycasin/g body weight. Cycasin was used in a 2.5 per cent solution of sterile physiological saline. Thus the volume of cycasin solution injected was 0.02 ml./g body weight. The solution was filtered before use and administered under the skin of the back to each mouse. Another group of twenty-one newborn mice, less than 24 h old, from the three mothers of the same strain, served as a control group. These mice were subcutaneously injected with 0.02 ml. of saline/g body weight in the same manner. The litters were kept in the same cage with their own mothers, which were maintained on a diet of CLEA (Central Laboratory of Experimental Animals) and water.

In the group which received a single subcutaneous injection of cycasin, nine out of sixty newborns (15 per cent) died 5-15 days after the injection and thirty-three (55 per cent) died 20-33 days after the injection (Table 1), while mice in the control group were healthy and developed normally. Forty animals (80 per cent) out of fifty-one animals which survived for more than 20 days showed ataxia and posterior paralysis. The sex of the affected animals was unrelated to the incidence of the disease. It was difficult to diagnose the neurological disorder in mice which died before they could walk.

The severity of locomotor difficulties was tentatively classified into the following several grades. Grade 1: slight posterior weakness with excessive swaying of the hindquarters and gait is slow. Grade 2: relatively slight ataxia, that is, a lack of co-ordination and exaggerated lifting of the hind feet with a characteristic "goose-stepping" gait. Grade 3: marked ataxia; animals stagger and stumble or fall down frequently when trotted, but are able to recover and stand up. Grade 4: complete paralysis of the hindquarters, but the animal is able to move, dragging its paralysed hindquarters.

These symptoms were irreversible and closely resembled those symptoms in cattle which had been fed cycad plant material². There was no appreciable loss in bladder, anal or tail functioning. Animals affected with the more severe ataxia usually died. During observation for 6 months after newborns were injected, the mothers were completely free of such disorders. Autopsies were performed on all mice which were dying or which had been killed in a moribund condition and which had survived for more than 20 days and showed symptoms of the neurological disorder after the injection of cycasin. Tissue from all the organs as well as the complete central nervous system was fixed in 10 per cent formalin. Routine methods of cutting, paraffin embedding and sectioning were used. The embedded tissue was sectioned and stained with haematoxylin and eosin. Duplicated slides of the central nervous system were stained with Luxol fast blue. The gross findings at autopsy were essentially negative. Histological changes were not found in any organs except the liver: animals which died a relatively short period after the injection of cycasin showed degeneration of the liver cells. In animals which survived for about 1 month after the injection, irregularity of liver cells in shape and size was a common finding. These histological changes in the liver were attributed to the toxicity of cycasin. Although detailed histological observations of the central nervous system are now in progress, a definite lesion to explain the neurological disorder has not yet been detected.

In another experiment, a total of fifty-eight adult male mice, of strain C57BL/6, 2 months old, received a single oral administration of cycasin by stomach tube. Eighteen mice received 1.0 mg cycasin/g body weight and ten mice received 0.5 mg/g. Cycasin was used as a 10 per cent solution dissolved in physiological saline. The cent solution dissolved in physiological saline. remaining thirty mice were given 0.3 mg cycasin/g body weight using a 5 per cent solution of cycasin. Most animals which had been given a large dose of cycasin died of an acute toxicity without neurological disorder within about 2 weeks after the administration of cyeasin. Follow-up observations have been carried out for more than 8 months in thirty-four survivors, but they have not shown any sign of the locomotor difficulties.

This investigation was supported by a US Public Health Service research grant from the National Cancer Institute.

BIOCHEMISTRY

Electron Spin Resonance and Optical Spectra of Haemoglobin-M Hyde Park

HUMAN methaemoglobins, M, form a class of variants in which the haems of two of the polypeptide chains contain ferric ions at all times, while the haems of the other two chains contain iron ions in either the ferric or the ferrous state. Haemoglobin-M Hyde Park (Hb-M HP) belongs to this group of methaemoglobins. It is characterized by a substitution of tyrosine for histidine in position 92 of the β chains. This is the fifth co-ordination position of iron. Only α -chains can be oxygenated, even though the oxygen affinity and Bohr effect are similar to those in Hb-A³.

In order to study the behaviour of the two pairs of chains further, I have analysed the electron spin resonance and optical spectra of Hb-M Hyde Park in two different forms. In one, all four chains are in met form—the ferric form of haemoglobin with a water molecule occupying the sixth co-ordination position of iron. In the other, the abnormal chains are in met, while the normal ones are in oxygenated condition. Iron of the latter is ferrous and an oxygen molecule is present in the sixth position of iron. We shall call these two forms met—met and met—oxy, respectively. When compared with measurements on met Hb-A and oxy Hb-A, information concerning the presence, or lack, of interactions between α and β chains of this variant is obtained.

Hb-M HP was separated from Hb-A by Dr Helen Ranney in the manner previously described (to be published). The preparation contained 80-85 per cent Hb-M HP in the met-oxy state. The transformation to met-met state is achieved by adding 1.3 potassium ferricyanide per haem, followed by dialysis against appropriate buffer.

Electron spin resonance measurements were performed in a Varian V-4500 spectrometer operating at about 9,000 Mc/s with a modulation frequency of 100 kc/s. All the electron spin resonance measurements were obtained in frozen solutions at 77° K. Optical spectra were taken at room temperature in a Spectronic 505 spectrometer.

The absorption signal of electron spin resonance in haemoglobin originates from the iron in the ferric form

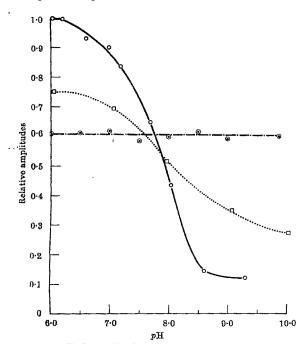

Fig. 1. Amplitudes of the electron spin resonance absorption signal at g=6 as a function of pH. O—O, Met Hb-A; O—·O, met—oxy Hb-M HP; $\square \dots \square$, met—met Hb-M HP.

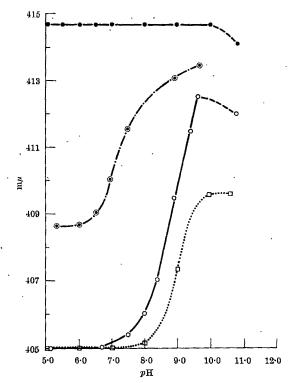

Fig. 2. The wavelength of the Soret band maximum as a function of pH.

One is a function of pH.

The wavelength of the Soret band maximum as a function of pH.

alone. The signal in methaemoglobin as A is characterized by a spectroscopic splitting factor $g_{\perp}=6$ (ref. 3). The signal from Hb-M HP appears at the same value of g_{\perp} but consists of a split absorption line, in contrast to the single line in met-Hb-A⁴, indicating a lower symmetry of the ligand field at iron in Hb-M HP than in Hb-A. The amplitudes of the absorption lines at different pH are directly proportional to the concentrations of ferric ions because no changes in shape of electron spin resonance lines are observed.

Fig. 1 summarizes the results of the electron spin resonance experiments. The amplitudes of the g=6 signal are plotted as a function of pH for three different samples, met Hb-A, met—met Hb-M HP and met—oxy Hb-M HP. Data are normalized with respect to the amplitude of the signal in Hb-A at pH 6.0, taken arbitrarily to equal one. All data refer to concentrations of $2\cdot 4g$ per cent.

The sharp decrease of the amplitude of electron spin resonance signal with pH in met Hb-A is a well known phenomenon⁵ and is caused by a transition from high to low spin state of ferric ions associated probably with the formation of hydroxide ions at the position occupied by water molecules at lower pH^5 . The pK of this transition occurs at about 7.8.

Only the ferric ions of the abnormal β chains contribute to the electron spin resonance absorption signal in metoxy Hb-M HP. It is apparent that no change in the amplitude of the signal, and therefore no change in the spin state of the ferric ions, occurs between pH 6.0 and 9.7.

The behaviour of met—met Hb-M \overrightarrow{HP} is intermediate between that of met Hb-A and met—oxy Hb-M HP. This strongly suggests that the normal α chains, when in met state, undergo a high to low spin transition similar to Hb-A. The β chains continue in the high spin state, as indicated by the remaining amplitude of the electron spin resonance signal at pH 9 and 10.

For optical spectra, the wavelength of the maxima of the absorption bands near 400 m μ , Soret bands, is plotted as a function of pH in Fig. 2. Met—met Hb-M HP shows a transition to longer wavelengths with increasing pH

which is less pronounced, however, than in met Hb-A. The width of the band, at half absorption maximum, is 30 m μ at pH 7.0 or less, and 33.5, 50 and 75 m μ at pH 8, 9 and 10, respectively. The width of the Soret band in met Hb-A is 30 mu below pH 8.5, and 38 mu at higher pH. The behaviour of met-met Hb-M HP indicates a superposition of two Soret bands, one arising from a chains, identical to met Hb-A, and the other one from β chains with a maximum at about 405 m μ at all pHbetween 5.0 and 10.4.

The behaviour of the Soret band in met-oxy Hb-M HP is intermediate between that of oxy Hb-A and met Hb-A. The width of the band is about 34 to 35 m μ at all pH, as in oxy Hb-A. There is no indication of a splitting of the band. Based on our previous interpretation, a superposition of Soret bands with peaks at 405 and 415 m μ would be expected. This should have resulted in a very broad band, or a split one with a maximum, independent of pH.

Fig. 3a is a plot of the extinction coefficient of the 541 mu band as a function of pH. The transition from a low to a high extinction coefficient in met Hb-A is associated with the transition from high to low spin⁸. Its pK is identical with the pK of the electron spin resonance transition. Met—met Hb-M HP has a less pronounced

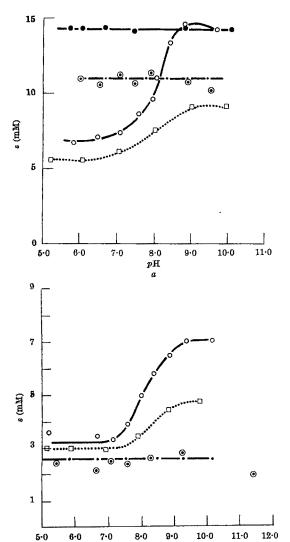

Fig. 3. a, Extinction coefficients at 541 m μ as a function of pH. • Oxy Hb-A; O—O, met Hb-A; O—·O. met-Oxy Hb-M HP; \square ··· \square , met-met Hb-M HP. b, Extinction coefficients at 600 m μ as a function of pH. O—O, Met Hb-A; O—·O, met-oxy Hb-M HP; \square ··· \square , met-met Hb-M HP.

pH

transition at the same pK. No transitions are observed in oxy Hb-A and met-oxy Hb-M HP. These results are entirely consistent with the independent behaviour of α and β chains in this abnormal haemoglobin and with the conservation of the high spin state in β chains at all pH. Identical results were obtained for the 576 mu band² (not shown).

The behaviour of the 600 mµ band is also consistent with our picture (Fig. 3b). The small amplitudes of the 630 mµ band made numerical comparisons difficult.

It can therefore be concluded that: (1) Ferric state of low spin is not formed in the haems of B, abnormal, The substitution of tyrosine for chains of Hb-M HP. histidine in the fifth co-ordination position of iron affects the charge distribution at the position of the sixth ligand, preventing a low spin complex forming at pH as high as 10. (2) There is no indication that the α , normal, chains in Hb-M HP behave any differently than in Hb-A, as far

as their magnetic and optical properties are concerned.

This work was supported by a US Public Health Service grant and by the Life Insurance Medical Research Fund. I thank Dr P. Heller for supplying the blood specimen from which Hb-M Hyde Park was obtained and Dr Helen Ranney for separating the Hb-MHP and for helpful discussions.

Synthesis of Macromolecules and Maturation of Starfish Ovocytes

DURING the maturation of amphibian eggs, 'Feulgen positive bodies appear in the cytoplasm^{1,2}: they become visible when the nuclear membrane breaks down and are undoubtedly of nuclear origin. Their appearance is not prevented by treatment of the eggs with actinomycin, puromycin or cycloheximide3, which block the maturation of amphibian eggs^{3,4}. According to Dettlaff⁴, actinomyoin suppresses maturation only during the initial hormone-dependent phase in Rana. In Xenopus we In Xenopus we found³ that all stages of maturation were sensitive to actinomycin.

The present investigation was undertaken in order to answer two questions. First, is an elimination of material which stains with Feulgen detectable during the maturation of starfish ovocytes? Second, is this maturation, which occurs spontaneously when ripe ovocytes are exposed to sea water, blocked by the inhibitors of RNA and protein synthesis?

Ripe ovaries of Asterias ruhens were placed in sea water from the North Sea. In April or May, more than 95 per cent of the ovocytes underwent maturation within 30 min. They were treated continuously with either pure sea water (controls), actinomycin D (20 $\mu/\text{ml.}$), puromycin (50 μg/ml.) or cycloheximide (20 μg/ml.). At various intervals of time, ovocytes were fixed with acetic Zenker and sections were stained in the usual way, with Feulgen and Unna. In two experiments, the incorporation of

Fig. 1.

 $^3H\text{-uridine}$ (6.6 \times 10-3 $\,\mu\mathrm{moles/ml.})$ into ovocytes undergoing maturation has been studied by autoradiography.

Results show some variability because of the heterogeneity of the egg population: for example, at zero time, 33 per cent of the ovocytes already have a degenerate germinal vesicle. As a result of an invasion of the nuclear sap by pre-existing cytoplasmic ribosomes, the region where the nuclear sap is mixed with the cytoplasm stains intensely with pyronine. No incorporation of uridine can be detected by autoradiography in this basophilic region. Such an invasion has been observed by electron microscopy during the maturation of Xenopus ovocytes (results in preparation).

The chromosomes become visible when the germinal vesicle has lost its membrane. In addition, an annular body which stains positively with Feulgen can be seen (Fig. 1). It is easily recognizable by its shape and by the fact that it stains more lightly with Feulgen than the chromosomes. It differs in two respects from the "large chromosome" described by Dalcq^{5,6} in starfish ovocytes undergoing maturation. Thus it can only be seen when maturation proceeds in a hypotonic medium, when it is found attached to the spindle. In contrast, the annular body is found during maturation in normal sea water and it always lies at some distance away from the spindle. In the ovocytes with intact nuclei, phase contrast observation of preparations stained with Feulgen shows that the nucleolus is often formed of two distinct zones; Feulgen positive material is associated with the denser of the two.

No appreciable changes occur during the first 10 min after treatment. After 20 min, more than 90 per cent of the ovocytes have undergone maturation and the chromosomes and the annular body are very visible in the basophilic Ovocytes which have been treated with evtoplasm. puromycin and cycloheximide are identical with the controls. After actinomycin treatment, a paradoxical effect is observed: the segregation of the granular and fibrillar constituents of the nucleolus is facilitated by actinomycin in unripe starfish ovocytes7, but is delayed by the same inhibitor in ovocytes undergoing maturation.

After 40 min, the structure of the cytoplasm has changed and, as described by Dalcq^{6,7}, cytasters are frequent. As in amphibian eggs8, their formation is not prevented by actinomycin, puromycin or cycloheximide. The chromosomes and the annular body migrate towards the cortex; the body always lies outside the spindle, at some distance from the chromosomes. Its frequency is higher in the eggs treated with actinomycin (63 per cent) than in the controls (36 per cent). This difference could be caused either by a condensation of the chromosomes and the annular body, induced by actinomycin (as we observed in amphibians3, or by a delay in the maturation produced by this drug. It is not uncommon to find one or two Feulgen

positive bodies in the central cytoplasm, in the control as well as in the treated eggs. Inhibition of the formation of the spindle and the migration of the chromosomes towards the animal pole is found when protein synthesis is blocked by cycloheximide or puromycin.

After 90 min, the majority of the controls have a spindle which is anchored in the cortex; some of them have already expelled their first polar body. Feulgen positive bodies can sometimes still be found in the centre of the egg but the annular body has usually disappeared. Actinomycin has definitely delayed or blocked meiosis; no polar bodies are seen and the condensed chromosomes are still in metaphase. The annular body is usually present. Maturation in eggs treated with puromycin is completely blocked and the chromosomes, which are often slender, usually remain in the centre of the eggs.

There are many similarities between the maturation of amphibian^{2,3} and starfish ovocytes: in both cases, maturation is blocked by inhibitors of RNA and protein synthesis. We have, however, been unable to demonstrate by autoradiography, in Asterias, the RNA synthesis which occurs in amphibians9. This failure could be a result of poor permeability to the precursors or to loss of radioactive material during the autoradiography procedure. The effects of the various inhibitors on the chromosomes are also the same in the two materials: actinomycin produces a condensation of the chromosomes, while puromycin and cycloheximide tend to induce their despiralization. both cases, Feulgen positive bodies appear in the cytoplasm during maturation and cease to be visible when the first polar body is expelled. There are many more in amphibian than in the starfish ovocytes, where the annular body probably represents a unique equivalent of the many granules found in amphibians1-3. The origin of these Feulgen staining bodies remains enigmatic. If one takes into account the facts that they have probably no centromere (because they are never attached to the spindle) and that they differ greatly in number in Asterias and Xenopus, one can venture the hypothesis that these bodies might correspond to the DNA of the cistrons of the nucleolar organizers, which are no longer needed when the nucleoli break down during maturation. This hypothesis derives from the fact that Xenopus ovocytes have hundreds of nucleoli and Asterias ovocytes only one.

We thank Merck, Sharp and Dohme for a gift of actinomycin D, and Dr A. Ficq and Mrs E. Hubert for useful discussions and technical help. This work was supported by Euratom.

Subcellular Localization of 5-Hydroxytryptamine and Histamine in Blood Platelets

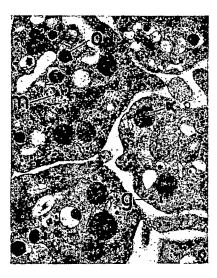

BLOOD platelets of various species contain particular, dense, osmiophilic organelles (dense bodies) which are somewhat smaller (500 to 2200 Å) than the a-granules. By combining electron microscopy and 5-hydroxytryptamine determinations, including experiments with reserpine, we have provided strong evidence that the

osmiophility of the organelles is caused by an accumulation of 5-hydroxytryptamine¹⁻⁴. Experiments with tyramine confirmed this view⁵. Here, we report attempts to isolate the dense osmiophilic bodies of platelets by density gradient centrifugation. Furthermore, the distribution of 5-hydroxytryptamine and histamine in various subcellular platelet fractions, including the dense bodies, was determined.

Blood platelets of rabbits, which contain a large number of dense bodies, were isolated, as previously described, and disrupted by ultrasonication. The incompletely destroyed platelets were removed by differential centrifugation and the remainder was centrifuged in a continuous density gradient (results in preparation for publication). In the various fractions of the homogenate, 5-hydroxytryptamine and histamine were measured by spectrophotofluorimetric procedures, and related to the protein content (determined colorimetrically). Furthermore, three principal fractions were submitted to electron microscopy after fixation with glutaraldehyde-osmium

tetroxide.

The three fractions, examined by electron microscopy, contained (from top to bottom) mitochondria, α-granules

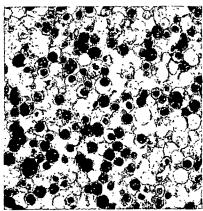

Fig. 1. Electron micrographs of intact isolated blood platelets of rabbits (above) and of isolated dense bodles (bottom layer) obtained by density gradient centrifugation from rabbit platelets (below) (\times 20,000). O, Osmiophilic organelle (dense body); a, a-granule; m, mitochondrium; g, glycogen granules.

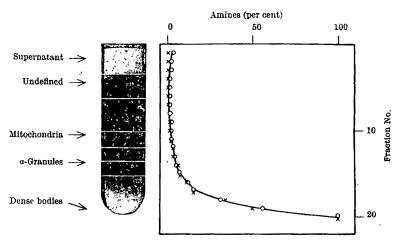

Fig. 2. Distribution of 5-hydroxytryptamine (5HT) and histamine in the various fractions of rabbit platelets. Each fraction, indicated on the abscissa, consists of nine drops of the centrifugate. The bottom layer, attached as a fine film to the tube wall, was dissolved in distilled water. The ordinate indicates the amine content (gmolar 5HT or histamine)µg protein) of each fraction as a percentage of that contained in the bottom layer (5HT or histamine of dense bodies = 100 per cent). Typical experiment. O, 5HT; ×, histamine.

and dense osmiophilic bodies. The fractions of α -granules and mitochondria were contaminated with other particles, including some dense bodies. The bottom layer, which was attached as a fine film to the tube wall, did not contain α -granules or mitochondria; it consisted of virtually 100 per cent vesicle-like structures. These measured 500–2200 Å in diameter and were surrounded by a single membrane. A large number of the vesicles were filled with a dense osmiophilic material, others were incompletely filled or empty. Ultramorphology and size of the organelles were similar to those of the dense bodies described earlier in intact platelets (Fig. 1).

The amount of 5-hydroxytryptamine in the bottom layer, containing the dense osmiophilic bodies, was much greater than in the other fractions (Fig. 2). In relation to the amount of proteins, the bottom layer contained over fifty times more 5-hydroxytryptamine than the total homogenate of platelets. In agreement with previous findings¹⁻⁴, these results therefore indicate a localization of platelet 5-hydroxytryptamine (which reduces osmium tetroxide¹) in particular, dense, osmiophilic organelles which, contrary to other views¹⁰, do not belong to the α -granules. The occurrence of empty organelles in the bottom layer is possibly caused by an artefact, because of the technical procedures such as ultrasonication, ultracentrifugation and fixation. It might, however, also reflect the true conditions in vivo, because in intact rabbit platelets empty and partly filled vesicles seem to be present besides completely filled ones (Fig. 1).

As previously found¹¹, histamine showed the same distribution as 5-hydroxytryptamine in the various

As previously found¹¹, histamine showed the same distribution as 5-hydroxytryptamine in the various fractions (Fig. 2). In the bottom layer which, in the present experiments, contained the highest amount of both amines, the molar ratio of histamine to 5-hydroxytryptamine was 0.42 ± 0.03 (eleven experiments).

The close parallel of the distributions of the two amines indicates that they are located in similar particles which are found chiefly in the bottom layer. It is conceivable that 5-hydroxytryptamine and histamine are present in the same organelles, which would be in contrast to previous assumptions. The possibility remains to be excluded, however, that in the bottom layer the osmiophilic organelles contain only 5-hydroxytryptamine, while the histamine (not reducing osmium tetroxide¹) is localized in the "empty" vesicles.

In conclusion, the high content of 5-hydroxytryptamine in the fraction of isolated dense osmiophilic bodies confirms the existence of particular platelet organelles storing 5-hydroxytryptamine. The results furthermore indicate that in rabbit platelets histamine and 5-hydroxy-

tryptamine are localized in the same or in similar subcellular structures.

We thank Professor E. F. Lüscher and Dr A. Siegel, Theodor-Kocher-Institute, Berne, for advice and technical help.

Distribution of Platelet Hexokinase and the Effect of Collagen

THE interaction of platelets with the subendothelial collagen, which is exposed when blood vessels are damaged, is believed to be of fundamental importance in haemostasis.

It has recently been shown that when collagen is added to washed human platelets there is a 30 per cent increase in platelet lactate production (in preparation). This increase occurs immediately, and in the presence of glucose is linear over 60 min. To investigate the mechanism of this increased lactate production, we have studied the effect of incubation of platelets with collagen on the activity of a number of platelet glycolytic enzymes. Particular attention has been given to the study of hexokinase because this enzyme is thought to have a rate-limiting role in glycolysis in platelets² and other tissues³⁻⁸.

Human platelets were obtained from the blood of normal volunteers. The blood was drawn through a 19-gauge non-siliconized needle into a 50 ml. siliconized syringe and rapidly mixed with 2 per cent ethylene diamine tetra-acetate (EDTA), 9 parts of blood to 1 part of EDTA. Blood from each donor was processed separately within 30 min of venepuncture. Platelet-rich plasma was prepared by centrifugation at 200g for 10 min at 4° C; this was then centrifuged at 2,000g for 20 min at 4° C. The supernatant was removed and the platelet pellet washed once in cold EDTA-Tyrode solution and resuspended finally in Krebs-Ringer bicarbonate buffer, pH 7.4, modified by replacing the calcium chloride and magnesium sulphate with 0.9 per cent sodium chloride. The final platelet suspension was free of aggregates and contained approximately 1×10^6 platelets per mm³. Erythrocyte and leucocyte contamination was less than 1 cell per 2,000 platelets. Two ml. aliquots of platelet suspension were incubated with either 0.2 ml. of collagen suspension, prepared as described elsewhere (Loder, Hirsh and de Gruchy, in preparation), or 0.2 ml. buffer for 10 min at 37° C. After cooling the incubation mixture in melting ice, the platelets were disrupted by adding 1 ml. of aqueous digitonin solution (1.5 mg/ml.) and gently

agitating the mixture at 4° C for 1 h. To obtain further disruption the suspension was then frozen and thawed three times in methanol at -70° C. It was found that phosphofructokinase was largely inactivated by the freezing and thawing procedure; with assays of this enzyme this step was therefore omitted. Enzyme assays were performed on either the whole cell lysate (total activity), prepared as described previously, or on the supernatant fraction (soluble activity), prepared by centrifugation of the whole lysate at 30,000g at 4° C for 20 min. The solutions for assay were kept at 0° C at all times and assays were performed within 3 h of disrupting the platelets. No significant loss of enzyme activity was observed over this period. All enzyme assays were carried out spectrophotometrically at 25° C using systems linked to the oxidation or reduction of pyridine nucleotides under conditions where the enzyme to be measured was ratelimiting. Optical measurements, all at 340 m μ , were made with a Gilford model 2000 multiple sample absorbance spectrophotometer or a Perkin Elmer UV137 with Leeds Northrup linear absorbance recorder. Assays were performed in a total volume of 2.5 ml. in a cuvette of 1 cm path-length. Enzyme activities were calculated from the change in optical density over a period during which the reaction rate was linear and expressed as µmoles of substrate utilized per min per 1011 platelets. The methods used were basically as previously described for red cell glycolytic enzymes, with minor modifications. The final concentrations of reagents in the assay systems are given

The results of enzyme assays performed on the supernatant fraction are shown in Table 1. There was a significant increase in hexokinase activity after platelets were exposed to collagen (t=7.36, P<0.01), the mean increase being 31 per cent. No such increase was observed with the five other enzymes examined.

Assays performed before and after centrifugation of the whole cell lysate revealed that activity of hexokinase, unlike that of the other glycolytic enzymes examined, was considerably greater in the preparation before centrifugation (Table 2). Furthermore, the difference in activity could be accounted for by assay of the washed precipitate. This suggests that some of the platelet hexokinase is attached to sedimentable cellular components.

The effect of collagen on total and soluble hexokinase activity is shown in Table 3. It is apparent that there is an increase in soluble activity but no corresponding increase in total enzyme activity. This suggests that collagen

causes release into the supernatant fraction of some of the hexokinase which is bound to sedimentable cellular com-

The existence of particle-bound hexokinase has been demonstrated in a number of other tissues¹⁰⁻¹³, and more recently mitochondrial hexokinase has been reported14-17. The exposure of platelets to collagen results in marked ultrastructural changes which are associated with disappearance of mitochondria and other cytoplasmic granules¹⁸. These changes are accompanied by a sudden increase in lactate production (Loder, Hirsh and de Gruchy, in preparation). The results presented here show that the interaction between platelets and collagen is also accompanied by an increase of about 30 per cent in soluble hexokinase activity in the platelet lysate. It seems possible therefore that collagen causes a release of particle-bound hexokinase into the cytoplasm and that this redistribution of enzyme activity contributes to the increased lactate production.

Table 1. ENZYME ACTIVITIES IN THE SUPERNATANT FRACTION BEFORE AND AFTER EXPOSURE OF PLATELETS TO COLLAGEN

AFTER EXPUSURE	OF PLATELETS TO CO	LLAGEN
Enzyme	Activity of 30,000 Platelets without collagen	y supernatant Platelets with collagen

Involvement of a Membrane Potential in the Synthesis of ATP by Mitochondria

Cockerell, Harris and Pressman¹ recently reported that when mitochondria which had been poisoned with rotenone were suspended in a potassium-free sucrose medium buffered with tris phosphate, the addition of valino-mycin led to a rapid loss of potassium, a rapid but smaller uptake of hydrogen ions, and a simultaneous net synthesis of ATP. This synthesis of ATP, apparently at the expense of a downhill movement of potassium ions, is extremely interesting, but it may be interpreted in more than one way. Cockerell et al. compared the ATP synthesis in their experiments with the ATP synthesis which seems to accompany reversal of the "sodium pump" in the red cell membrane², and suggest that the synthesis in mitochondria is similarly brought about by the reversal of an ATP-driven cation pump. The outward movement of potassium ions is, they suppose, directly coupled to ATP synthesis. This explanation may be correct, but it does require that a significant part of the efflux of potassium should take place through the pump pathway, and therefore—given that only the inner mitochondrial membrane serves as an effective barrier to small ions-valinomycin should act specifically at the pump sites, for example, by facilitating the access of potassium ions to those sites.

An alternative hypothesis is that valinomycin merely confers on the inner mitochondrial membrane the high permeability to potassium ions which it is known to confer on lipid bilayers3,4, lipid micelles5 and on red cell membranes6.7, so that in the presence of valinomycin the potassium gradient sets up an electrical potential. By driving hydrogen ions inwards, or anions outwards, through a mechanism which coupled ion movements to phosphorylation⁸, this electrical potential could serve as the immediate source of energy for ATP synthesis. If the potassium concentration within the mitochondrial inner membrane is 145 mmolar, and the external potassium concentration is 0.4 mmolar, the potassium equilibrium potential is 149 mV. Not enough is known about the permeability of the inner mitochondrial membrane, either to potassium or to other ions, to predict the potential which would in fact be reached after treatment with valinomycin, but it could easily be 100 mV. At this level, and assuming that there was sufficient buffering to prevent the development of a substantial pH difference across the membrane, the inward movement of 4 g equiv. of hydrogen ions-or the outward movement of 4 g equiv. of hydroxyl ionscould make available about 9,000 calories of free energy.

The proposed hypothesis requires that the inward current driven by the electrical potential should be chiefly carried by ions traversing a pathway coupled to phosphorylation, rather than by ions penetrating the valinomycin channels. In experiments on lipid bilayers treated with valinomycin, Lev and Buzhinsky's have shown that when potassium and hydrogen ions are present in equal, low concentrations it is the hydrogen ions which penetrate more readily. In the mitochondrial experiments, however, the difference of perhaps six orders of magnitude between the concentration of potassium ions and the concentration of hydrogen ions makes it reasonable to suggest that the hydrogen flux through the valinomycin channels could be small compared with the potassium flux. The flux of hydrogen ions through the valinomycin channels might also be limited by the curious interaction between less and more-penetrating ions noticed by Mueller and Rudin in experiments on lipid bilayers, although the behaviour of hydrogen ions was not investigated in those experi-

Cockerell et al. point out that exit of potassium and entry of hydrogen ions are not necessarily associated with the formation of ATP because no ATP synthesis accompanies the large loss of potassium and gain of hydrogen ions which take place when nigericin is added to suspensions of mitochondria in conditions similar to those used in the valinomycin experiments. The way in which nigericin acts to promote this exchange of cations is not understood, but nigericin is a monobasic acid. If part of the molecule behaves as a negatively charged cation-carrying shuttle unable to penetrate the membrane in the charged form (compare the role of guaiacol in Osterhout's classical model¹⁰), the catalysed exchange of potassium and hydrogen ions would be strictly 1:1 and would not lead to a transfer of charge. An exchange of this kind could not generate an electrical potential capable of maintaining an inward current, and therefore, by hypothesis, could not lead to ATP synthesis. It follows that the absence of ATP synthesis when potassium: hydrogen exchange is brought about by nigericin cannot be regarded as evidence that the action of valinomycin is at specific sites.

Interpreted in this way, the experiments of Cockerell et al. provide the first evidence that a membrane potential might be involved in the synthesis of ATP by mitochondria.

Chemical Radioprotection of mRNA in a Nirenberg Cell Free System

In 1964, Wacker and Chandra¹ showed that the incorporation of polyU-directed 14C-phenylalanine into the acid soluble fraction of a Nirenberg cell free system² was inactivated by gamma irradiation. Atter a dose of about 80 krads, inactivation reached the 50 per cent level. Experiments of Eckert³ provided data which showed a steeper dose/response curve for irradiated polyU.

Following our recent investigation on radiosensitivity of mRNA synthesis4-6, we decided to study the behaviour of mRNA with respect to the possibility of its chemical radioprotection when subjected to ionizing radiation in a Nirenberg cell free system. In non-dividing yeast cells⁵, doses of X-rays of 120 krads do not cause more than 48 per cent suppression of mRNA synthesis and for this reason they are not suitable for radioprotection experiments. As the data presented in this communication indicate, however, Nirenberg's cell free system is a very suitable model for radioprotection investigation at the molecular level. In Fig. 1 is shown the effect of chemical radioprotection of polyU when 0.015 per cent concentration of cysteamine hydrochloride is used. Further dilution leads to a decrease in radioprotective activity: 0.0015 per cent cysteamine hydrochloride in the system is almost completely ineffective and the corresponding dose/response curve goes down and approaches the control curve. Several experiments were carried out using 0.15 per cent cysteamine hydrochloride, but a marked suppression of up to 70 per cent was found in this case in non-irradiated samples.

The strong dependence of radioprotective activity on the concentration of cysteamine hydrochloride in the range 0.015-0.0015 per cent seems to support deoxygenation of the irradiated polyU-solutions caused by cysteamine. This, however, is not in accord with Eckert's observation3 that a decrease of the oxygen content in polyU solutions during irradiation lowers the radioresistance of polyU, as checked by 14C-polyphenyl-alanine synthesis in a cell free system. This suggests that a specific cysteamine" radioprotection cannot be excluded.

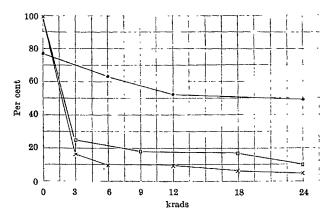

Fig. 1. Cysteamine radioprotection in irradiated polyU solutions. E. coli B was cultivated on an aerated glucose-bullion medium. The incubated S-30, cell free fraction (Inc. S-30) was prepared according to the classical technique of Nirenberg*. Samples of 0-5 ml., each containing 3,000 µg of Inc. S-30, were incubated for 40 min at 35° C after addition of 0-004 µmoles of ¹*C-phenylalanine (specific activity 121 mc./mmole). Water solutions of polyU (100 µg/ml.) were irradiated with cobalt-60 gamma rays (4,000 g equiv. of radiation) at a dose rate of 600 r./nin (ferrous sulphate dosimeter); the temperature during irradiation was maintained at 4° C. Samples were treated using a filter disk technique according to a modification given to us in personal communication by A. Wacker and P. Chandra: 0-1 ml. from each test tube was transferred onto 3 cm filter disks and was then immersed as follows: 2 h in 10 per cent TCA (5° C). 20 min in 5 per cent TCA (5° C), 20 min in 5 per cent TCA (5° C), 20 min in 5 per cent TCA (5° C), 20 min in 5 per cent TCA (5° C) and twice in ethanol/ether (1:1). Radiometric determinations were made using a scintillation mixture consisting of 0-4 per cent diphenyloxydiazol, 0-01 per cent POPOP in xylene. Each point on the curves represents an average of three independent samples. ×, PolyU; \(\preceq\), polyU and 0-015 per cent cysteamine hydrochloride;

Steric Course of the Succinic Dehydrogenase Catalysed Exchange of Hydrogen between Succinate and Water

Succinic dehydrogenase (succinate: (acceptor) oxidoreductase E.C. 1.3.99.1) catalyses the oxidation of succinate by various electron acceptors to fumarate. Although the mechanism of the reaction is not yet understood, it has been shown¹ that the overall process involves removal of one H_R- and one H_S-atom² from adjacent carbon atoms of the substrate (Fig. 1a); this corresponds to a trans elimination from the antiperiplanar conformation of succinate, as in Fig. 1b.

In anaerobic conditions, the same enzyme is known to catalyse the exchange of hydrogen atoms between water and the methylene groups of succinate3, with fumarate acting as an accelerator of the process. The stereochemistry of this exchange has been the object of conflicting reports. Using Keilin and Hartree particle bound enzyme preparations, one group of workers claimed that incubation of succinate in deuterium oxide leads to a preponderance of monodeuterated molecules possessing (S)-configuration, as inferred from the comparison of the positive plain optical rotatory dispersion (ORD) curve of the recovered succinic acid with that of an authentic In similar conditions, fast exchange with sample⁶. the medium was also reported for the HR-atom* of the methylene group in (S)-chlorosuccinate, Fig. 1c, although in a later paper, it was stated that the methine hydrogen of this substrate exchanges with the medium faster than HR on the adjacent carbon atom. More recently a second group, working with the same enzyme preparation, reporteds the almost exclusive formation of monodeuterated succinate molecules and maintained on the basis of ORD measurements that the exchanged succinic acid is devoid of optical activity, thus implying lack of stereospecificity for the exchange reaction.

Preliminary experiments carried out by the late Mr U. Steinemann in Zurich (unpublished results) led us

* Note that, notwith standing the different indices, Hz of Fig. 1c is sterically equivalent to Hz of Fig. 1a.

to reinvestigate this problem. Our results differ considerably from those previously reported.

Anaerobic incubations of succinate in deuterium oxide were carried out in the presence of an enzyme preparation purified by the method of DerVartanian and Veeger*. Different batches of the enzyme showed specific activities between 200 and 240 U/mg and were almost free of fumarase activity. In order to follow the time dependence of the exchange reaction, samples were withdrawn at different time intervals and the reaction was stopped in each case by heating to 100° for 5 min. After removal of the denatured protein by centrifugation, the reaction mixtures were chromatographed on Dowex 1 (formate form) according to Busch et al. 10. Clean separation of succinic, malic (whenever present) and fumaric acid was achieved. The samples of succinic acid were further purified by repeated crystallization from water.

Determinations of isotopes were carried out with a Hitachi-Perkin Elmer RMU-6A mass spectrometer at low voltage. Succinic acid was admitted to the normal inlet system of the instrument at 180°. The amount of the different deuterated species was evaluated on the basis of the ion peak at m/e = 56 arising by the loss of carbon dioxide from the thermally preformed anhydride. Optical rotations were measured with a Bellingham and Stanley-Bendix 'Polarmatic 62' spectropolarimeter, using a cell of 1 cm path length and aqueous solutions containing 20-50 mg/ml. of succinic acids. The ORD curves of authentic (-)-(R)-succinic acid (and, as a check, of unlabelled succinic acid) were obtained at the same time.

Data from a typical experiment are recorded in Table 1. All the samples with a substantial deuterium content showed a negative plain ORD curve, similar to the one which is characteristic for (-)-(R)-succinic acid- d_1 (ref. 6). This is true not only for the five samples of the table but also for twenty-three additional samples obtained from eight further incubations. It is evident from the data of the table that relevant amounts of d2-molecules are formed beside the monodeuterated ones even at an early stage of the reaction. The initially observed ratio $(d_1:d_2 \equiv 2:1)$ rules out the possibility that the early appearance of d2molecules is caused by a further exchange of preformed monodeuterated molecules. If reversible trans dehydrogenation of succinate is operative in the formation of these d₂-molecules, the species produced would be (optically inactive) meso-succinic acid-d₂. This is supported by the observed satisfactory agreement between di-content and percentage of optical activity for samples 2F and 3F. Comparison of sample 3F with an artificial mixture of succinic acids (22 per cent d1, 78 per cent d0) by infrared spectroscopy¹¹ revealed that the d_2 -molecules in 3F were indeed preponderantly (but not exclusively) of the meso-The consistently and remarkably high value for the optical rotation of samples which have been allowed to interact with the enzyme for a longer time (for example, 5F and 6F) requires that, as the exchange reaction proceeds, a relevant amount of d1-molecules is converted to (R,R)-succinate-d2 through the exchange of the remaining labile HR-atom. By the same exchange, optically active (-)-(R)-succinate- d_3 will accumulate at the expense of (optically inactive) meso-d2-molecules.

We have also observed a definite preponderance of (S)deuterated succinic acids when succinate-d4 was incubated

				Table :	1			
	Reaction							Per cent

6F	12	5	22.5	37	27	8.5	22·6°	108

The reaction mixture contained 300 moles disodium succinate, 100 moles disodium fumerate, 270 moles disodium hydrogen phosphate, 30 moles potassium hydrogen phosphate, 5 mg succinic dehydrogenase.

Volume 3.2 ml. in deuterium oxide; temperature 25° C, pD = 7.8; anaerobic conditions.

* Mean of the values at eight-fourteen different wavelengths as compared with the ORD curve of optically pure (-)-(R) succinic acid-d₁.

anaerobically with the enzyme in water; though here the isotopic species which increase most rapidly at first are succinate-d2 and succinate-d0.

Regardless of the precise mechanism of the reaction, it is clear from our results that the enantioscopic H-atoms of the substrate must have different fates and that the HRatoms are more prone to exchange with the medium than their Hs counterparts. This finding contrasts with the claim of Hüfner et al.12 to have demonstrated that all four hydrogen atoms of succinate are equivalent in the exchange

Bioassay of Captan by Zebrafish Larvae

CAPTAN (N-trichloromethylthio-4-cyclohexene-1,2-dicarboxyimide) is an agricultural fungicide of low mammalian toxicity, and its residues* in agricultural products are considered to offer less risk than most pesticides. A recent report¹ draws attention to the mutagenic and teratogenic properties of captan, which has been observed to increase the mutation rate in bacteria (Escherichia coli), to inhibit mitotic division in the cell cultures and to induce physical abnormalities in chicks treated in the embryonic stage.

We are developing a general bioassay method for pesticides using zebrafish larvae. During this investigation we noted a particularly unusual response by captan. Although captan can be detected either chemically or biologically against fungal conidia2, the zebrafish larvae test shows promise in its convenience, rapid reaction, sensitivity and reproducibility.

The zebrafish, Brachydanio rerio (Hamilton-Buchanan), is an ornamental aquaria fish, 1.5 to 2 in. long, with length-

wise zebra stripes. This oviparous species can be bred in the laboratory throughout the year, providing large numbers of eggs which at room temperature require only 3 days to hatch. An individual fish produces 150-600 eggs at an interval of 10-15 days and a stock of 150 mature fish has been found sufficient to obtain enough eggs and larvae for tests with pesticides. The stock is kept in two aquaria with a capacity of 15 gallons, which are maintained at 26° C±1° C and with a filter outside the aquaria for bubbling clean air through the water. The fish are fed on dry commercial fish food and live mosquito larvae. One feeding in the morning is usually sufficient, but three feedings a day may be required if the fish are being used to produce large numbers of eggs.

Eggs are collected in a separate aquarium which is maintained in the same conditions of temperature and aeration as the stock aquaria are. As the species breeds at daybreak, the breeding arrangements are made the preceding evening. After the last feeding of the day, a number of gravid (plump) female fish with twice as many males are isolated in special breeding traps (with 10-mesh screen floor) which are hooked on the walls of the breeding aquarium. Underneath the traps, on the aquarium floor, finger bowls are provided for the collection of eggs. Early in the morning the fish drop their eggs within approximately 30 min. The bowls are taken out. the eggs are separated from faecal matter and debris. placed in Petri dishes with distilled water and allowed to develop. The embryos develop rapidly and larvae are produced in 3 days. The larvae hatch out with considerable embryonic yolk and need no feeding or special care before being used when they are 4 days old.

The larvae were unaffected by ethanol or acctone at concentrations up to 1 per cent (v/v). Standard solutions of recrystallized captan (m.p. 173° C) were prepared in acetone and 0.2 ml. of these solutions were diluted to give a final volume of 50 ml. The tests were made in glass dishes 1.5 in. high and 3 in. in diameter with 50-70 four day old larvae. There was no mortality in the 0.4 per cent acetone control used for the tests. Captan exerted a rapid and drastic effect on the larvae. At a concentration of 1 p.p.m. it strongly excited the larvae after exposure for 5 min and this excitation continued for another 30 min: the larvae became severely affected, lost the power of movement and went into a state of coma. After a further 10 min the larvae started dying and were all dead in the following 50 min (Fig. 1). The death of

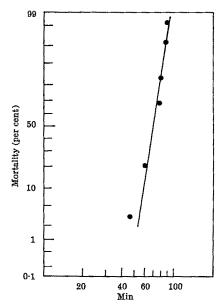

Fig. 1. Response of *Brachydanio rerio* larvae to 1 p.p.m. captan within 90 min.

^{*} Captan residue levels permissible in seventy-three fruits and vegetables in Canada, 40 p.p.m.

the larvae from captan poisoning was invariably associated with an observable head injury (Fig. 2) in which the eye balls, while still retaining connexions with the optic tissues, were blown out of the sockets and the head was ruptured into lateral halves to give a bicephalous appearance. This dramatic head injury resulted in appearance. immediate death and was used as an index in mortality

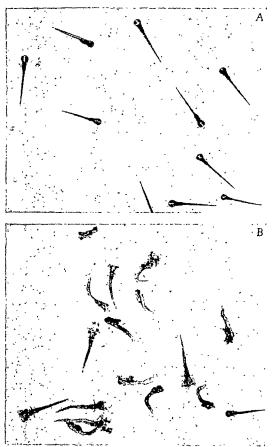

Fig. 2. Larvae of *Brachydanio rerio* before (A) and after (B) exposure to 1 p.p.m. captan for 75 min.

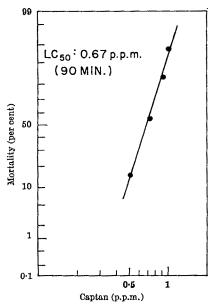

Fig. 3. Dosage-mortality response of *Brachydanio rerio* larvae to captan (mortality counts after exposure for 90 min).

counts for developing the larval response curves shown in Figs. 1 and 3.

Ninety-eight per cent of larvae died in 90 min at a concentration of 1 p.p.m. of captan, and a standard dosage-mortality curve (Fig. 3) can be prepared in this period of time for a rapid assay of microgram quantities of captan. Both the rapid kill and the head injury seem to be specific to captan, because these effects were not observed in similar tests with other pesticides including DDT, dieldrin, malathion, parathion, carbaryl, 2,4-D and warfarin.

Captan is not reported to be toxic to fish (personal communication, J. R. Thomas), and the unusual sensitivity of zebrafish larvae is probably a case of selective toxicity of captan.

Hydroxyproline-O-glycosidic Linkage of the Plant Cell Wall Glycoprotein Extensin

PRIMARY cell walls contain a protein, extensin, which is rich in trans 4-L-hydroxyproline¹⁻³. I suggested earlier that this protein could cross link wall polysaccharides4; if some of these cross linkages were labile, it would provide a chemical basis for changes in cell wall plasticity which are necessary for extension of plant cells. The recent isolation of several glycopeptides, rich in hydroxyproline from enzymatic digests of tomato cell walls, confirmed the inference of a covalent carbohydrate-protein linkage in The chemical composition and properties of these glycopeptides also led me to the preliminary conclusion that attachment of the carbohydrate is by a glycosidic link through the hydroxyl group of hydroxy-This rather unexpected possibility receives additional support from results presented in this communication, describing the isolation of hydroxyproline-Oglycosides from partial alkaline hydrolysates of tomato cell walls. These cell wall preparations account for more than 95 per cent of the hydroxyproline of the cells³. Most of this hydroxyproline (about 70 per cent) can be released as hydroxyproline glycosides. The method is based on the fact that glycosidic linkages are usually stable to those alkaline conditions which lead to rapid hydrolysis of peptide bonds.

Suspension cultures of the species shown in Table 1 were grown and walls prepared as previously described3,7. Dry walls from cell suspensions of tomato (Lycopersicon esculentum Mill.) were mixed (10 mg/ml.) with a saturated solution of barium hydroxide (0.43 normal) and were heated for 8 h at 90° C in a stirred stoppered flask. The contents of the flask were cooled, neutralized with 1 normal sulphuric acid, and centrifuged for 15 min (or until clear) at 1,000 r.p.m. in a bench centrifuge. The supernatant fraction was evaporated to dryness, taken up in 5 ml. of 0.1 molar acetic acid and fractionated on a $120 \text{ cm} \times 3.8 \text{ cm}$ 'Sephadex G-25' column (void volume 360 ml.). Samples from each tube were assayed for free hydroxyproline by oxidation with sodium hypobromite and subsequent reaction with Ehrlich's reagent8. Peptide-bound hydroxy-

proline does not react.

Fig. 1 shows two peaks of non-peptide bound hydroxyproline. Peak II has an elution volume (762 ml.) similar to that of other monomers and is free hydroxyproline.

Cell walls were isolated from cultured material unless otherwise indicated, After hydrolysis for 8 h in 0.43 normal barium hydroxide at 90° C, portions of the neutralized hydrolysate were directly subjected to paper electrophoresis at pH 1.9 for 2 h at 155 V/cm. In these conditions free hydroxyproline migrated 40-45 cm towards the cathode. Detection of the spots was by the method described. The fastest moving compounds (columns 4 and 5) are minor commonate. * Solanum tuberosum also gave a large spot with Rhypro = 0.44.

Peak I contains hydroxyproline which is not peptide bound because it reacts with Ehrlich's reagent as free hydroxyproline, while its elution volume (650 ml.) indicates a molecular weight considerably greater than that of free hydroxyproline. Peak I subjected to paper electrophoresis at pH 1.9, followed by the usual test for hydroxyproline (isatin followed by Ehrlich's reagent9), gave three main and two minor spots. Other species gave similar compounds (Table 1). Chromatography of the G-25 peak I on the cation exchange resin 'Aminex' (Fig. 2) separated the three main hydroxyproline compounds. Their relative migration rates through the 'Aminex' column were inversely related to their relative migration rates on electrophoresis at pH 1.9. For convenience, we designate the most slowly moving electrophoretic component of the series as hypro-X1 (peak I on the 'Aminex' column shown in Fig. 2). Further analysis by acid hydrolysis and paper chromatography showed that the hypro-X compounds also contain arabinose (compare Fig. 2). No other sugars or amino-acids were detected. Hydroxyproline and arabinose estimations (Table 2) indicate an empirical formula for hypro-X1 as hypro₁ arabinose₄, and hypro-X3 as hypro₁ arabinose₃. Hypro-X2 seems to be a mixture (but not of hypro-X1 and X2): thus, first, it contains roughly equal amounts of cis and trans 4-hydroxyproline;

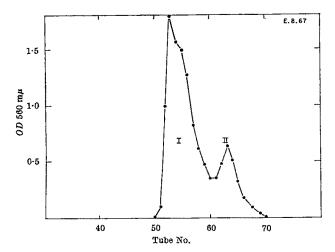

Fig. 1. Fractionation of the partial alkaline hydrolysate of primary cell walls of tomato cell suspension cultures. Dry tomato cell walls (2·3 g) obtained from a suspension culture were treated with 230 ml. of 0·43 normal barlum hydroxide for 8 h at 90° C. After neutralization with sulphuric acid, centrifugation and evaporation as described in the text, the soluble material was fractionated on a 'Sephadex C-25' column. Fractions of 12 ml. were collected of which 0·1 ml. samples were assayed for hydroxyproline. These hydrolysis conditions release all the wall hydroxyproline, 80-90 per cent of which then reacts as non-peptide bound hydroxyproline.

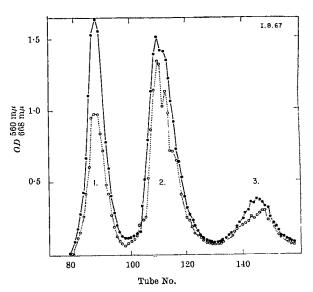

Fig. 2. Further 'Aminex' fractionation of a partial alkaline hydrolysate from tomato cell walls. The 'Sephadex G-25' peak I was pooled, evaporated, taken up in 2 ml. of buffer, pH 1·9 (8·7 per cent acetic, 2·5 per cent formic acid v/v), and placed on a 25 × 1 cm 'Aminex' (200-325 mesh) column in the H + form. The column was eluted with buffer pH 1·9 and 4 ml. fractions were collected. These were assayed for hydroxyproline (○ · · · · ○, method in text) and for arabinose (◆ — ◆) by heating the sample for 90 min at 90° C with 8 normal hydrochloric acid containing 0·1 per cent orcinol and 0·1 per cent hydrated ferric chloride, and then reading the OD at 688 mµ.

second, the hydroxyproline arabinose molar ratio falls between that of hypro-X1 and hypro-X3; and third, the 'Aminex' separation shows a consistently skewed hypro-X2 peak (Fig. 2). (The cis 4-hydroxyproline arises by racemization during the alkaline hydrolysis, as this isomer cannot be detected in acid hydrolysates of cell walls.)

Table 2. HYDROXYPROLINE GLYCOSIDES OBTAINED FROM TOMATO CELL WALLS: MOLAR RATIOS OF ARABINOSE/HYDROXYPROLINE

	Found	Theoretical	Hypro epimer
Hypro-X1	3.7	4	Trans
Hypro-X2	3.4	?	Cis and trans
Hypro-X3	2.7	3	Mainly cis

The following data indicate the most likely point of attachment between the arabinose and hydroxyproline: (1) Alkali stability rules out an ester linkage and acid lability makes an ether linkage unlikely. (2) After paper electrophoresis the hypro-X series did not react with an alkaline silver nitrate reagent¹⁰. Thus the reducing group of arabinose is blocked, indicating a glycosidic link between arabinose and hydroxyproline. (3) The secondary amino group of the hydroxyproline is free (for example, it can be cyanoethylated by the method of Fletcher¹¹ and therefore cannot be involved in the glycosidic linkage. (4) The hydroxyproline carboxyl group is free, as estimated from the neutral behaviour of hypro-X on electrophoresis at pH 6.5, and from the observation that hydroxyproline in peptide linkage (including dipeptides such as glycyl hydroxyproline and hydroxyprolyl glycine), unlike free hydroxyproline, cannot be oxidized to products which torm chromogens with Ehrlich's reagent.

In sum total, these data indicate that in the higher plants so far examined (Table 1) an arabinose oligosaccharide is attached as a substituent on the hydroxyl group of hydroxyproline, that is, carbon 1 of arabinose is linked glycosidically to carbon 4 of hydroxyproline. Thus a picture of extensin emerges in the form of a polypeptide backbone where most of, if not all, the numerous hydroxyproline residues (about 30 per cent of all the amino-acid residues in tomato cell walls) are involved in a new and hitherto unsuspected carbohydrate-protein linkage. The short arabinose oligosaccharides may serve as attachment regions for other wall polysaccharides. A short sequence of extensin, for example, consisting of two hydroxyproline residues and two or three other amino-acid residues, could be regarded as the cross link between two polysaccharide chains. Thus a small amount of extensin is potentially capable of cross linking a hugely disproportionate amount of wall polysaccharide. In this way even the minute amounts of wall hydroxyproline, characteristic of some species3, could play an important part in determining the properties of the primary cell wall.

Activation of Glucose-6-phosphatase of Rat Liver at High pH: Differential Response of Basal and Induced Activities

THE significance of increases in levels of glucose-6-phosphatase following induction of diabetes or treatment with glucocorticoids has been a matter of some controversy1,2. A contributory factor to this controversy has been that the actual level of enzyme activity determined in a particular sample is very dependent on the chosen conditions of assay. Thus, citrate, a buffer commonly used in earlier studies, is now known to be an inhibitor of the enzyme, the degree of inhibition depending markedly on the pH of the assay3. Pretreatment of the enzyme with detergents activates the enzyme but also labilizes it, while treatment of the enzyme at high pH has been shown to result in a similar activation without parallel labilization4. Activation by either treatment, however, has been shown to alter both the pH optimum of the enzyme and the Kmfor substrate4,6. A further complication has been that some workers have studied the enzyme activity in well washed microsomal preparations while others have used whole tissue homogenates or crude particulate fractions. Moreover, even when using such crude preparations some workers have made no attempt to correct data thus obtained for the activity of non-specific acid phosphatases of lysosomal origin.

In connexion with a study on possible changes in the localization of certain enzymes in response to nutritional or hormonal treatments we have been concerned to monitor glucose-6-phosphatase activity in rat liver. In view of the above considerations it was decided to assay this enzyme activity in washed microsomal preparations and also to correct the observed phosphate release for the residual activity of non-specific acid phosphatases. Activity was measured both before and after activation by incubation in ammonium hydroxide. In order to avoid ambiguities, resulting from possible changes in Km, the assays were performed at a relatively high concentration of substrate (80 mmolar). Activities were

determined in cacodylate buffer at pH 6.1. As shown by Stetten and Burnetts, this pH is on the alkaline end of the plateau of optimum pH for the unstimulated enzyme while being close to the peak in the pH-activity curve of the ammonia-activated enzyme. We have confirmed this observation for microsomal preparations from livers of rats of all groups included in the present study. In some experiments, citrate buffer at $p\bar{\rm H}$ 6·1 was also used in parallel assays. Activity was linear with time under all assay conditions employed.

Briefly the experimental procedure was as follows. Microsomes were isolated from homogenates of livers from Wistar rats, washed once and resuspended in 0.25 molar sucrose containing I mmolar EDTA (pH 7.2). The volume of the suspending medium was such that the preparations contained the equivalent of 0.5 g of liver per ml. The protein content of such suspensions did not vary significantly with age or pretreatment of experimental animals. Glucose-6-phosphatase activity of freshly prepared microsomal fractions was determined essentially as described by Stetten and Burnett⁵ except that the buffer used was 0·1 molar cacodylate, pH 6·1. Suitable corrections were made for the small content of contaminant inorganic phosphate of the substrate and for the activity of non-specific acid phosphatases?. Activation by ammonium hydroxide was carried out as described by Stetten and Burnett⁴. Activities are expressed as µmoles of inorganic phosphate released in 10 min at 30° by 0·1 ml. of microsomal suspension (corresponding to 50 mg liver). The diabetic rats, used in this study, had been treated by intraperitoneal injection of alloxan (15 mg/100 g body weight) and were sacrificed when glycosuric.

Initially, we compared activities of preparations from young adult rats (about 150 g) which had been well fed or subjected to mild fasting (up to 24 h). As expected, it was observed consistently that fasting tended to increase the glucose-6-phosphatase activity of the liver microsomal preparations. Two other observations, however, were also consistently made. One was independent of the pretreatment of the animals. This was that when enzymatic activity was measured in citrate buffer, not only was there inhibition of activity (by comparison with assays carried out in cacodylate buffer), but activity was further decreased following pre-incubation of microsomal pre-parations at high pH (see Table 1). This was in marked contrast to the findings of Stetten and Burnett, and in contradistinction to the stimulatory effect of such pretreatment on activity as assayed in cacodylate (see Table 1 and below). This unexpected finding could be interpreted in terms of an increased exposure of the active site to the incubation medium following treatment at high pH. Such an exposure might render the enzyme more susceptible to inhibition by citrate.

The second observation which was consistently made was that the degree of stimulation of glucose-6-phosphatase activity (measured in cacodylate buffer), after treatment of microsomal preparations, at high pH, was greater in the case of the fasted rats than in the case of the animals fed ad libitum. This observation was confirmed when further studies were made with a group of adult rats (200 g to 300 g). This distinction between fed and fasted rats was almost invariably maintained for given matched pairs of animals (of either sex). For an evaluation of the data, however, it was not found prac-

Experimental details and definition of unit of activity are given in the text. The data presented are for eleven rats in the weight range 130 g to 160 g. Data are given as mean values \pm standard errors of means.

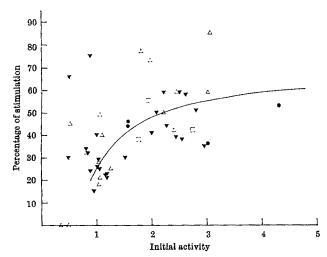

Fig. 1. The relationship between initial activity (units defined in text) and degree of stimulation by treatment at high pH of rat liver microsomal preparations. Φ , Rats 30 to 40 g; Δ , rats 100 to 200 g; Ψ , rats 200 to 300 g; Π , diabetic rats. The line is an arbitrary "theoretical" curve for two co-existent forms of enzyme (see text).

ticable to divide animals into fed and fasted groups because the extent of the fasting in some cases was only a few hours and the variability in enzyme activity among control animals was quite wide. There was thus some overlap in enzyme activity among the groups of animals. It was therefore decided to analyse the data in terms of initial glucose-6-phosphatase activity of the microsomal preparation (measured in cacodylate buffer) and degree of stimulation of this activity following pretreatment at high pH in the conditions described.

The results are plotted in Fig. 1, activity being expressed per 50 mg wet weight of liver. (Relative activities were shown to be essentially similar when activity was expressed in terms of microsomal protein.) It can be seen that, at least over a range of initial activity up to 2.0, the degree of stimulation by pretreatment at high pH seems to increase with initial activity. Thereafter the degree of stimulation seems to remain relatively constant. (The derivation of the line drawn in Fig. 1 will be discussed.)

The relationship between initial activity and degree of stimulation is highly significant for the entire group of animals tested (including some younger rats, weight 30 to 40 g, but not including the diabetic animals) (see Table 2). The relationship is also significant when young adult rats or older animals are treated as separate groups. Although not included in the statistical analysis, it can be seen from Fig. 1 that the data for adult rats rendered diabetic with alloxan fit well with the corresponding data for animals with high initial activities induced by fasting.

These conclusions are not likely to be caused by any false assumptions regarding the relatively minor correction for the activity of non-specific acid phosphatases (which were not significantly activated by the high pH treatment). Essentially the same pattern would have emerged had no correction at all been made for this activity. Moreover, the conditions of pre-incubation at high pHwere not critical for this demonstration. Indeed, subsequent studies revealed that microsomal preparations of

Table 2. Significance of difference in degree of stimulation of microsomal preparations of initially low and high activity respectively

The initial activity limit of 1.56 set for dividing the animals into groups of low and high initial activity for statistical analysis was chosen arbitrarily by inspection of Fig. 1. Data are given as mean values \pm standard errors of means.

low initial activity were fully activated by incubation for 10 min in the conditions referred to, while preparations of high initial activity (from fasted or diabetic animals) only reached their maximal activity after incubation for about 1 h. The distinction between preparations of low and high initial activity would therefore have been even more marked had a longer period of preincubation been routinely employed.

These findings indicate that, in the well-fed animal. an important proportion of the microsomal glucose-6phosphatase is in a form which is not greatly stimulated by treatment at high pH. When enzyme activity is increased following fasting or by diabetes, the "new" enzyme is in a form which is more susceptible to stimulation. Whether the "new" enzyme derives from the basal enzyme, or from an inactive precursor or by de novo protein synthesis is at present obscure. Assuming that the activities are quite separate, however (as suggested by Freedland and Harper⁸), it is possible to derive theoretical curves for the relationship between initial activity and degree of stimulation by selecting some quite arbitrary values for three parameters. These are the basal activity for all animals, the degree of stimulation of this basal activity by treatment at high pH and the degree of stimulation of all "new" enzyme following this treatment. Making the assumptions that the basal activity is 0.9 units (see here), and that the degrees of stimulation of basal and "new" enzyme are 20 per cent and 70 per cent. respectively, the line in Fig. 1 is obtained.

The satisfactory fit of the arbitrary curve to the experimental points is, of course, very tenuous evidence for the hypothesis of two, co-existent forms of the enzyme. It is hoped to resolve this question by direct fractionation procedures, taking advantage of the difference in properties between "basal" and "induced" enzyme activities revealed in this study.

In confirmation of our observations, it has recently been reported that microsomal glucose-6-phosphatase activity from livers of alloxan-diabetic rats is stimulated by detergent treatment to a greater extent than is the corresponding activity of normal rats.

BIOPHYSICS

Potassium Ion Activity in the Cytoplasm and the Vacuole of Cells of Chara and Griffithsia

A CHARACTERISTIC of plant cells is that they have adjoining phases of different physico-chemical properties. These are the cell wall, the cytoplasm and the vacuole. Unequal distributions of ionic activities between these phases are expected, as are electrical potential differences. Investigations of the ion-exchange processes in algal cells of the Characeae1, and analyses of the cytoplasmic and vacuolar composition of centrifuged cells2, confirm the existence of separate intracellular phases. Although an electrical potential difference between the cell vacuole and the medium bathing the cell has long been established, confirmation of potential steps between the remaining phases of plant cells was only found later.

During the past few years it has been possible to observe potential differences at the junctions between the cell wall and medium^{3,4}, and between the cytoplasm and the vacuole^{5,6}. Although our knowledge of the distribution of electrical potentials in the adjoining phases of the plant cell has substantially increased, the details of the distribution of ionic activity between the same phases have remained obscure. First attempts have, however, been made to determine the ionic activities of potassium ions and chloride ions in the vacuolar sap^{7,8} and chloride ions in the cytoplasm⁹ of Characeae cells.

The present work is concerned with determining the potassium ion activity (a_{K+}) in the vacuole, cytoplasm and the surrounding medium, with concurrent measurements of the potential differences between these phases. The investigation was made with cells of the green, freshwater alga Chara australis R.Br. var nobilis A.Br. and the red marine alga Griffithsia sp. The cells of C. australis were cultivated in artificial conditions, and before the experiments were kept for at least 2 days in an artificial pond water (1.0 mmolar sodium chloride+ 0.1 mmolar potassium chloride+0.1 mmolar calcium chloride). The cells were dissected from the whorls at the nodes; whorl cells are sufficiently transparent to enable the phases of cytoplasm and vacuole to be distinguished. The cells used were 2-5 mm long and 0.5-0.8 mm in diameter. Collected Griffithsia cells with dimensions of approximately 1.5×1.7 mm were kept for several days in an artificial sea water (potassium chloride, 10 mmolar; sodium chloride, 470 mmolar; magnesium chloride, 25 mmolar; magnesium sulphate, 25 mmolar; sodium bromide, I mmolar; sodium bicarbonate, 2.5 mmolar; calcium chloride, 11.5 mmolar).

For the intracellular measurement of $a_{\mathbb{R}^+}$ and of potential differences, two microelectrodes (one filled with 3 molar potassium chloride and the other a potassium ionsensitive microelectrode) both with tip diameters of about 1μ were inserted while being viewed through a microscope (magnification \times 180). Simultaneous records were obtained of two potential differences, one between the microelectrode and potassium ion-sensitive microelectrode both maintained in the same cell phase, and the other between the intracellular and a reference microelectrode. The distance between the two intracellular electrodes was $40-80\mu$, the angle between them being 30° .

Microelectrodes sensitive to potassium were designed to measure a_{K+}. The tips contained a precipitate of either sodium cobaltinitrite or dipicrylamine, and the microelectrodes functioned as potassium ion electrodes in the concentration range 10-3-1 molar potassium chloride. The selectivity coefficient was usually 0.2, the best value achieved was 0.12 and in the experiments with Griffithsia cells the value was 0.46. The microelectrodes sensitive to potassium were calibrated in solutions of potassium chloride and sodium chloride before, and on conclusion of, the experiment. The accuracy of measurement of a_{K+} in the presence of sodium ions in the ratio [K+]: [Na+]= 2.5:1 was in the vicinity of 10-15 per cent. The half-time for the response of the sensitive microelectrodes, when the concentration was changed ten-fold, was about 3-4 sec. The resistance of these microelectrodes was in the range $10^{10}\text{--}3 \times 10^{10}~\Omega$. The measurements of a_{K^+} and of potentials were carried out in August and September 1967 with the temperature of the surrounding medium 20°-22° C.

The first potential step of -60 mV was registered when the microelectrode was inserted into the cell wall of *Chara*. Immediately after the cell wall was penetrated a second potential step of about -100 mV was observed which corresponded to the cytoplasmic phase. The

typical thickness of the flowing cytoplasm was 15 to 20μ and the entrance of the microelectrode into the cytoplasm induced local cessation of cytoplasmic flow and the initiation of a large cytoplasmic clot (cloud) about 40μ thick. A few minutes later this cloud began to disappear. To measure a_{K^+} in the vacuolar sap, and the vacuole potential, the microelectrodes were inserted to a depth of $150-200\mu$.

Measurements could be made in the cytoplasm for as long as 20 min, then as the electrode became sealed off from the cytoplasm the potential dropped to that of the cell wall. When recording the two potential differences between the three electrodes as described, the beginning of the microelectrode transition into another phase could be established with great accuracy. It was thus possible to be sure that both microelectrodes were in the same phase, which served as a control in measuring a_{K^+} and the potential differences. In the *Griffithsia* cells the cytoplasm adhered to the microelectrode tip and followed it like a trail, and the cytoplasmic potential could be measured for a period of many hours.

The activity of potassium ions in the cytoplasm of C. australis cells was found to be $2\cdot 3$ times greater than that of the vacuolar sap (Table 1). In the Griffithsia cells, however, the reverse was observed, and the cytoplasmic $a_{\mathbb{K}^+}$ was $2\cdot 2$ times less than that of the vacuole. It is interesting to note that $a_{\mathbb{K}^+}$ in the cytoplasm of the marine and the freshwater algae were in the ratio of only $1\cdot 4$ to 1, while in the vacuolar sap the ratio was $7\cdot 3$. When microelectrodes became sealed off after insertion in the cytoplasm, the potential difference corresponded to $a_{\mathbb{K}^+}=7-10$ mmolar.

For comparison with the results obtained for ion activity, analyses were made of the vacuolar sap, using a flame photometer. It was found that the *Griffithsia* cells had an average value (unpublished results of G. P. Findlay and A. B. Hope) of 546 mmolar for [K+] vac and 63 mmolar for [Na+] vac. It we assume that the activity coefficient, γ , in the vacuolar sap of the marine algae is equal to γ of artificial sea water, that is, approximately 0.68, then $a_{\mathbb{K}^+}$ calculated from results for the potassium ion concentration would be equal to 370 mmolar. This value corresponds to the mean intracellular $a_{\mathbb{K}^+}$ measured in living cells (Table 1).

The activity coefficient in the vacuolar sap of the C. australis cells was established by determining the chloride ion activity, $a_{\rm Cl}$ -, using the method of microsample extraction. The mean value of $a_{\rm Cl}$ - was equal to 84 mmolar. The activity coefficient in the solution of potassium chloride, the concentration of which corresponds to the observed $a_{\rm Cl}$ -, is equal to 0.75. The potassium concentration in the vacuolar sap of C. australis (5 cells) was found to have a mean value of 60 ± 3 mmolar which corresponds to $a_{\rm K}=45$ mmolar. This is closely related to the activity measured with potassium ion-sensitive microelectrodes.

Comparisons can now be made between the equilibrium potassium ion-potential, $E_{\mathbb{K}^+}$ (Table 1), for the cytoplasmic and vacuolar phases, calculated on the basis of experimental results for $a_{\mathbb{K}^+}$, and the potentials measured in the corresponding phases, using the Nernst equation. It is clear that the equilibrium potentials of potassium ions between artificial pond water and the cytoplasm or the vacuole of the C. australis cells, and between artificial

Table 1. Potassium ion activities compared with measured potential differences (Eoi, mv) and estimated nernst potentials ($E_{\rm K}+$, mv) in cells of Chara australis and Griffithsia

Cells	Phase	Potassium ion (mmola	ır)	E K +(m∇)	Eci (mV)

* Activity coefficients in artificial pond water and artificial sea water are taken to be 0.96 and 0.68, which are the coefficients for sodium chloride solutions of concentrations 1.3 and 553 mmolar, respectively.

sea water and the cytoplasm of Griffithsia cells, are nearly equal to the observed potential differences. This suggests that potassium ions are in electrochemical equilibrium in these phases.

On the other hand, the electrochemical potentials of potassium ions in the vacuole and the cytoplasm of Griffithsia cells differ significantly. The difference, $\Delta\mu_{K^+}=\mu_{K^+\nu ac}-\mu_{K^+cyt}$, is equal to 1,100 cal. mole-1 with the gradient directed from the vacuole to the cytoplasm. It is therefore suggested that there is an active transport of potassium ions from the cytoplasm to the vacuole.

PHYSIOLOGY

Effects of Dehydration on Blood Viscosity and on Distribution of Plasma Proteins in Experimental Macroglobulinaemia

A GREAT variety of plasma cell tumours has been induced in mice and transplanted in successive generations of these animals^{1,2}. The tumours secrete large amounts of myeloma proteins and make it possible to examine various problems concerning the myelomas and dysproteinaemias. Usually, as the concentration of myeloma protein rises in the plasma of affected animals, the concentration of normal protein diminishes2. A similar reduction of normal plasma proteins in humans with dysproteinaemias has been related either to decreased synthesis or to increased catabolism of normal protein fractions. As yet, no data have appeared concerning the plasma concentrations of abnormal and normal proteins in experimental macroglobulinaemia. The plasma cell tumour designated MOPC-104E secretes large amounts of macroglobulin (IgM). Mice bearing this tumour resemble humans with macroglobulinaemia, in that both display an elevated blood viscosity which is related to the plasma concentration of IgM and modified by the haematocrit⁵⁻⁷. It was of additional interest to determine whether these mice also resembled human macroglobulinaemics3 with respect to the relative intravascular concentrations of IgM and non-macroglobulin (non-IgM). This investigation examines this question. In addition, an attempt was made to alter the intravascular distribution of proteins by changing the osmotic balance of the animals through dehydration.

Plasma cell tumour MOPC-104E was transplanted to female Balb/c mice by subcutaneous injection into the lower abdominal wall. Four to six weeks later the tumours had grown to large solid masses, and animals were selected for dehydration, which was accomplished by depriving them of drinking water for 24 h. Dehydrated and nondeprived mice bore tumours of approximately the same size and had carried them for the same length of time. Animals were anaesthetized with sodium pentobarbital and blood was obtained by cardiac puncture. Blood was drawn through a 23 gauge needle into a syringe containing sufficient heparin to yield a final concentration of 4-8 U, ml. blood.

Microhaematocrit determinations were performed on all blood samples. The apparent relative viscosity (hereafter abbreviated as "viscosity") of blood was measured at 37°C with a capillary viscosimeter operating at a shear rate in excess of 1,000 reciprocal seconds. (at a pressure of -100 mm of mercury, 0.1 ml. water took 1 sec to pass through the capillary, which was 306µ wide and 36 mm long). At such high rates of shear, blood viscosity is no longer affected by shear rate; thus values in the present study represent the asymptotic portion of the curve relating shear rate to shear stress10.

A portion of each blood sample was centrifuged in 'Wintrobe' tubes and the plasma was decanted. plasma protein was determined with the biuret procedure¹¹ and IgM concentrations were measured by radial immunodiffusion¹². Subtraction of the IgM concentration from the total protein gave the concentration of non-IgM.

The effects of dehydration are indicated in Table 1. Blood viscosity doubled, as did the concentration of IgM, results which are consonant with earlier data suggesting a linear relationship between these variables. The increases in haematocrit and total protein concentration also contributed to the rise in blood viscosity 6.10, and shifts in the relative concentration of individual, unmeasured protein fractions may have influenced the magnitude of the viscosity elevation6.

Although dehydration increased the IgM level by 100 per cent, the increase in total protein was only 30 per cent (Table 1). Thus, while the IgM concentration rose during dehydration, the intravascular concentration of non-IgM (total protein minus IgM) decreased (Fig. 1).

Study of the non-deprived or control mice (Fig. 1) indicates that, in these animals also, the IgM level was inversely related to the concentration of non-IgM, a relationship also observed in humans with macroglobulinaemia3. The data in Fig. 1 suggest that similar factors may control the intravascular distribution of proteins in both the dehydrated and the control macroglobulinaemic animals, because the points representing the two groups of mice overlap and appear to be distributed along a common curve.

Alterations in the rates of synthesis or catabolism of IgM and non-IgM may have affected the distribution of intravascular proteins in these mice^{3,13}. The present data do not cast light on the question. The data do suggest, however, that osmotic factors played a part in adjusting the relative concentrations of IgM and non-IgM, at least during dehydration. Water deprivation increased the haematocrit by 25 per cent, but a parallel and equal reduction in total body water would have resulted in death¹⁴. Thus water must have been lost in disproportionate amounts from the vascular compartment, a phenomenon known to occur during mild to moderate dehydration¹⁴. This preferential loss of intravascular water was accompanied by an almost equivalent (25 per cent) decrease of intravascular non-IgM, which suggests that normal proteins followed water in its passage out of On the other hand, the IgM level rose the vessels. markedly and, in fact, the percentage increase in IgM concentration was four times greater than the increment The basis for the greater increase in in haematocrit.

Table 1. MACROGLOBULINAEMIC MICE

	Haematocrit	Blood viscosity	IgM (mg/ml.)	Total protein (mg,ml.)
Not dehydrated (11 mice)	$32 \pm 4*$	4.3 ± 1.0	32 ± 11	69 ± 6
Dehydrated	40 ± 4	$8 \cdot 0 \pm 2 \cdot 7$	63 ± 29	91 ± 20

^{*} Mean \pm S.D. All differences between the two groups of macroglobulinaemic mice are significant at 0.01 level (Mann-Whitney test).

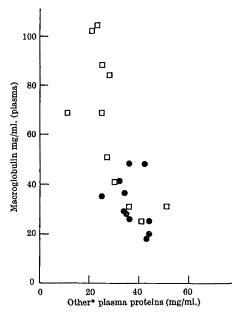

Fig. 1. Macroglobulinaemic mice. The greater the IgM level, the lower the concentration of non-IgM (Spearman rank correlation coefficient = -0.81, P < 0.01). * Total protein minus IgM. •, Control; __, dehydrated.

plasma IgM is not understood, but the increase itself suggests that IgM molecules could not readily follow the outward movement of water. Data from hydrated humans with macroglobulinaemia also indicate an inability of IgM to leave the vascular compartment¹³. Thus 80 per cent of the body's IgM is located intravascularly in macroglobulinaemia while only 40 per cent of the body's albumin, 6.6S gamma globulin, or transferrin are similarly distributed^{3,13}. In the present experiments the intravascular concentration of IgM apparently could not be readily altered to meet the requirements of the new osmotic situation engendered by the loss of intravascular water. The decreased level of non-IgM thereby takes on even more importance as a homeostatic mechanism for keeping intravascular osmotic pressure within tolerable bounds.

Disodium Cromoglycate (FPL 670) ('Intal'*): a Specific Inhibitor of Reaginic Antibody-Antigen Mechanisms

CHROMONE derivatives exhibiting unusual biological activity have been studied in these laboratories for several years. One of these, disodium cromoglycate (FPL 670), has been found to inhibit specifically the liberation of the mediators of anaphylaxis initiated by the interaction of antigen with reagin type antibodies. It is neither a bronchodilator nor an anti-inflammatory agent and its action is distinct from that of corticosteroids.

In experiments on an asthmatic volunteer, inhaling the compound inhibited the acute effect of subsequent antigen inhalation¹. In patients suffering from allergic asthma, inhalation of this compound was followed by clinical improvement2.

Disodium cromoglycate is the sodium salt of 1,3-bis-(2-earboxychromon-5-yloxy)-2-hydroxypropane. It is an odourless, white, hydrated crystalline powder moderately soluble in water but practically insoluble in alcohol. Physical investigations (elementary analysis, infrared, ultraviolet, nuclear magnetic resonance and mass spectra) were consistent with the assigned structure

The compound inhibited the passive cutaneous anaphylactic (PCA) reactions in monkeys, sensitized with human reaginic serum, when the compound was given intradermally with the antigen, but did not affect the skin reactions to intradermal histamine, 5-hydroxytryptamine or bradykinin. Antigen induced bronchoconstriction in anaesthetized marmosets, sensitized intravenously with human reaginic serum, was substantially reduced by

disodium cromoglycate.

Homologous PCA reactions with reagin-like antibody in rats, using both the egg albumen/B. pertussis³ and Nippostrongylus brasiliensis⁴ systems, showed substantial inhibition in the presence of the compound. Although the compound inhibited the PCA reaction it failed to affect the skin lesions induced by compound 48/80.

In contrast, in guinea-pigs, homologous PCA reactions with precipitating antibody were unaffected, as were aerosol or intravenous antigen induced bronchospasm and the release of histamine and SRS-A (slow reacting substance-anaphylaxis) from actively or passively sensitized lung in vitro.

The release of histamine and SRS-A from portions of chopped human lung, passively sensitized with human reaginic serum, has been measured after exposure to specific antigen(s) in vitro5. Inhibition with disodium cromoglycate was found over a narrow range of concentrations.

In an in vitro system in which contractions of human bronchial chain, exposed to passively sensitized and shocked human lung, were used to simulate the supposed events in an attack of allergic asthma, FPL 670 at 10 µg/ml. caused a significant reduction (40 per cent) in the contractile response.

It was considered important to study the effect of the compound on those antibody systems concerned with immunity. No adverse effect was found on several in vitro virus/antibody neutralizing systems including influenza A, polio virus type II, vaccinia and herpes simplex with human and rabbit antisera.

Likewise no effect was found on the LD₅₀ in mice of mouse adapted polio virus, nor on their protection by

* Trade mark-Fisons Pharmaceuticals, Ltd.

Salk vaccine. No effect was observed on the neutralization of Clostridium welchii type A α -toxin by specific antiserum nor on the cytotoxic behaviour of rabbit anti-HeLa on HeLa cells in vitro. Nor did it interfere with any of the several bacterial agglutinating systems tested.

Further in vivo work was carried out on the effect of the compound on the passive protection of guinea-pigs with diphtheria antitoxin, on the development of immunity and response of immune mice to pneumococcus and on the development of experimental tuberculous lesions in guinea-pigs. In addition, an examination was made of the rate of production of antibody and the titre achieved in monkeys to T₁ coliphage. In all these in vivo systems no change in the normal pattern was observed over the range of doses administered.

Disodium cromoglycate has few general pharmacological effects. Relatively large doses (up to 100 mg/kg) given intravenously, intraperitoneally or to the cerebral ventricles in conscious animals from a wide range of species produced negative or only weak non-specific effects in various behavioural studies. Only in the dog were marked effects observed, intravenous injection of moderate doses (for example, 8 mg/kg) causing immediate collapse and transient apnoea with rapid recovery.

In studies of anaesthetized animals, large doses of disodium cromoglycate had only weak inconsistent effects on the cardiovascular and respiratory systems of the cat, pig, monkey, guinea-pig and rat. In anaesthetized dogs, doses as small as $10~\mu g/kg$ elicited reflex mechanisms originating in the pulmonary and coronary circulations producing bradycardia, hypotension and in some cases apnoea. In marmosets, however, the compound caused a rise in blood pressure and heart rate with little effect on respiration.

Studies with the new compound on bronchial tone in anaesthetized guinea-pigs demonstrated little activity. It had no direct action on human bronchial chain nor did it antagonize the responses to histamine, SRS-A or acetylcholine. The compound showed no significant effect in several anti-inflammatory tests nor did it have any consistent influence on the anti-inflammatory activity of hydrocortisone.

Disodium cromoglycate had no significant effect on several other functions studied including steroid metabolism, gastrointestinal mobility and urine and bile flow. It had little effect on the ciliary activity of either isolated frog oesophagus or human bronchial epithelium. The compound had no direct action on Trendelenburg's reflex of isolated guinea-pig ileum, neither did it antagonize the response of the ileum to histamine, 5-hydroxytryptamine, acetylcholine, nicotine, substance P, bradykinin or SRS-A.

The absorption, distribution and excretion of disodium cromoglycate have been studied in a variety of laboratory animals. Following oral administration, only a very small proportion (less than 0.5 per cent) of the dose was absorbed. After inhalation of the powder aerosol, only a small proportion of the dose reached the peripheral lungs, a major part being trapped in the upper respiratory tract. Plasma and lung tissue levels indicated that the powder reaching the peripheral lungs was rapidly and completely absorbed. The compound was rapidly eliminated, the major portion unchanged, via the urine and bile; no accumulation could be detected in any tissue even after repeated daily intramuscular injections. Studies of the urinary excretion and plasma levels in human volunteers have suggested that the same general pattern applies in man.

Disodium eromoglycate has been shown to be relatively non-toxic. Thus in *in vitro* tests a concentration of at least 5 mg/ml. was required to produce effects on the morphology of HEp2 cells and chick embryo fibroblast cells, and on the migration of guinea-pig macrophages. In acute toxicity tests in small laboratory animals, the LD_{50} on parenteral administration was usually between 2,000 and 4,000 mg/kg, while in a prolonged test in rats

no toxic effect resulted from ninety daily subcutaneous injections, except at doses greater than 30 mg/kg. The only pathological lesion produced in any of these tests was an inflammation and degeneration of the renal tubules. Neither this nor any other toxic effect was found in 90-day inhalation studies.

No teratogenic effects were seen in rabbits in which the compound was given intravenously daily throughout

pregnancy in doses up to 250 mg/kg.

Disodium eromoglycate had few general pharmacological effects, was rapidly excreted and seemed to have a low order of toxicity. The compound appeared to inhibit specifically the anaphylactic process initiated by reaginic antibody—antigen interactions. This novel property may permit a more specific treatment of allergic disease, especially of the lung, and will undoubtedly contribute to basic knowledge in these areas.

The results given here represent the combined efforts of the staff of the Research Departments at Holmes Chapel

too numerous to name individually.

I wish to thank Dr Geoffrey Taylor, of Manchester Royal Infirmary, for valued advice and work on immunological problems, and Dr A. J. O'Hea, Robroyston Hospital, and Dr L. G. Bruce, Victoria Infirmary, Glasgow. who performed the study on tuberculous infection.

ATPase Activity at the Functional Contacts between Retinal Cells which produce S-potential

According to Cajal1, the horizontal cells of the teleost retina are arranged in three superimposed tangential layers formed by the external, medial and internal horizontal cells. Cajal classified the horizontal cells as short axon (Golgi II) cells and showed that radially oriented apical processes make contact with the receptor Golgi studies and ultrastructural studies on the teleost retina (refs. 2 and 3 and unpublished results of V. Parthe and myself) confirm Cajal's description of these cells which in certain teleosts are enormous compared with the bipolar cells in the same retinal layer. tangentially oriented extensions were not found in the external horizontal cells in Parthe's Golgi material. Such extensions of the medial and internal horizontal cells do not exceed in length the diameter of the cell body. Axon-like structures were not seen by Parthe or myself in any of the horizontal cell layers. In ultrastructural work4 each row of horizontal cells appears as a reticulum in which the cells are interconnected by membrane to membrane apposition of their lateral processes. Yamada and Ishikawa³ described in the carp, shark and ray retinae "fused membrane structures" at the apposition areas between the short lateral processes of the horizontal cells. But specialized junctions were not seen between horizontal cells belonging to different layers. These findings have been confirmed (Fig. 1) and similar fused membrane structures have been seen between stellate amacrine cells and between interstitial amacrine cells, in the regions where membrane to membrane contacts are formed between adjacent cells (my unpublished work).

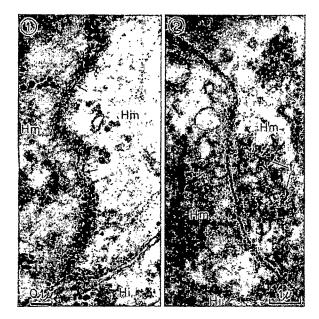

Fig. 1. Section of a Mugil brasiliensis retina showing partially two medial horizontal cells (Hm) and one internal horizontal cell (Hi). Zones of fused membranes alternate with zones of apposed membranes (arrows) at the lateral contacts between the two medial horizontal cells; no synaptic vesicles are visible. There are no fused membrane structures at the apposed membranes of the medial and internal horizontal cells. Glutaraldehyde-osmium post-fixed material. (\times c. 58,900.)

Fig. 2. Formalin fixed material incubated in Wachstein-Meisel medium and post-fixed in esmium. The ATPase reaction product is seen as lead precipitate at the fused membrane structures. Precipitate is less abundant at the apposed membranes of the medial and internal horizontal cells. f_* Fibrils (\times c_* 8,180).

Light and electron microscopy shows that all the cells, which are of a giant size in certain teleost retinae, form tangential networks which are continuous throughout the retina (ref. 5 and unpublished results of V. Parthe and myself). Synaptic vesicles have not been observed in the region of the fused membrane structures (Fig. 1).

Torack⁶ demonstrated high ATPase activity in the vicinity of the plasma membrane of oligodendroglial cells, while in the astroglia the ATPase was confined to processes in contact with neurones. Marchesi et al.⁷ found, in the rat retina, ATPase activity at the cell borders between glia and glia, and glia and neurones, but not between neurones. Novikoff et al.⁸ demonstrated the presence of an ATPase, which apparently is not of the transport type, at the interface between the Schwann cell and the non-myelinated axon in the peripheral nerve of the rat, and the interface between the ganglion cell and its satellite cells in the dorsal root ganglion.

The present attempts to demonstrate ATPase activity were carried out on teleost (Mugil brasiliensis) retinae incubated in a solution containing lead salt by the method of Wachstein and Meisel modified by Torack⁶. Retinae fixed in glutaraldehyde or hydroxyadipaldehyde gave negative results. In formalin-fixed material, ATPase reaction products were constantly found at the fused membrane structures at the lateral contact region between neighbouring cells of different horizontal cell networks. Fig. 2 shows the fused membrane structure of a lateral contact area between two medial horizontal cells; fused membrane zones alternate with apposed membrane zones. Fig. 3 shows that a positive reaction for ATPase activity is also found at the fibrillar structures, which are seen perpendicular to the fused plasma membranes of the horizontal cells. ATPase activity, in the form of electron dense granules, is more abundant at the fused areas. ATPase reaction products were scarcely apparent along the plasma membrane of the horizontal cells (Fig. 2), and scattered granules were occasionally observed in the cytoplasm. Mitochondria appear free of the reaction product.

A total inhibition of the ATPase reaction (Fig. 4) was achieved by adding nickel nitrate $(1\times10^{-2}\ \mathrm{molar})$ or L-cysteine $(5\times10^{-3}\ \mathrm{molar})$ to the final concentration of the Wachstein–Meisel medium. An almost complete inhibition was obtained with sodium fluoride $(6\times10^{-2}\ \mathrm{molar})$, whereas ouabain $(5\times10^{-4}\ \mathrm{molar})$ had no effect.

The ATPase stimulated by sodium and potassium⁹, which seems to be implicated in ion transport across cell membranes, is inhibited by the lead salt contained in the Wachstein-Meisel incubation medium¹⁰. Thus the ATPase positive reaction shown at the fused plasma membrane structures in this work seems not to be the result of the presence of the cation transport ATPase⁸. This ATPase shows similar characteristics to that observed by Torack⁶ in oligodendroglial processes; both are resistant to formalin but not to glutaraldehyde and hydroxyadipaldehyde.

The S-potentials of the luminosity (L) type originate in the large horizontal cells, whereas the chromatic (C) responses are recorded from the stellate and interstitial amacrine cells11. These potentials, evoked by light stimulation, are membrane potential changes, which show a lateral spread several mm away from the illuminated area. The spreading velocity of the L-response and of the hyperpolarizing C-response has been shown to be about 0.35 msec12. The calculated conduction time across one external or one medial horizontal cell is of the order of 0·1 msec and 0·2 msec, respectively, which is too short a time to account for any synaptic delay. The tight junctions found between glial cells in the optic nerve of Necturus and the frog are assumed to represent low resistance connexions for electrical interactions between neighbouring cells¹⁵. The "tight junctions" between adjacent supramedullary neurones in fish have been shown to operate as electrotonic junctions which permit electrical transmission between adjacent neurones16. The fused membrane structures described here are structurally and functionally different from tight junctions. The horizontal cell membrane is electrically inexcitable¹³, which excludes the possibility of an electrical synapse and of a spread of excitation by means of local ionic current flow. Negishi (unpublished results) has

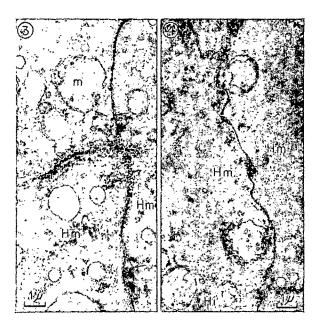

Fig. 3. Formalin fixed material incubated in Wachstein-Meisel medium and post-fixed in osmium. The ATPase reaction product is seen at fibrils (f), which are perpendicularly attached to the fused membrane structures of two medial horizontal cells (Hm). Precipitate is less abundant at the apposed, non-fused area (arrows). m, Mitochondria $(\times c. 16,360)$.

Fig. 4. Formalin fixed material incubated in Wachstein-Meisel medium containing nickel nitrate $(1\times 10^{-2}$ molar), and post-fixed in osmium. Absence of reaction product is evident. m, Mitochondria (\times c. 10,470).

recently confirmed that the behaviour of the S-potential producing membrane is not influenced by electrical ionic current flow and that S-potential spread from cell to cell in a given network is unrelated to ionic current flow.

It has been demonstrated that the S-potential function is strictly dependent on aerobic metabolism and that the membrane potential of S-cells is strongly influenced by temperature changes, which indicates a dependence on enzymatic systems¹¹. But the high membrane potential level (70 mV) of the S-cells produced by anoxia is a diffusion potential. It was suggested that the S-potentials depend on a plasma membrane respiration and that the spread of excitation in a given network is related to the function of an ATP-producing electron transfer system^{6,11}. The intercellular transfer of excitation within the S-cell networks "occurs only at specialized regions ('transferapse') where the apposed plasma membranes are partly fused'".

Most of the ATP formed by glucose oxidation is produced within the mitochondria, and because the mitochondrial membrane is relatively impermeable to ATP, a special system exists for transferring energy to the extramitochondrial space¹⁴. ATPase is a specific enzyme for the liberation of energy from ATP, so it is reasonable to assume that both ATP and ATPase are present at the same cellular locations. The question of the origin and function of the ATP hydrolysed by the non-transport ATPase at the fused plasma membrane structures in the retina arises. The respiratory chains are constituents of the mitochondrial membrane14, and therefore it is suggested that this ATP is formed by respiratory chains located in the fused plasma membrane structures, probably for the transfer of excitation from cell to cell within the S-cell networks. The ATPase found close to the cell surface is probably related to a mechanism for the spread of the S-potential along the plasma membrane.

I thank Dr Gunnar Svaetichin for his suggestions and help, Mrs Carlota Koteff and Mr Francisco Gil for technical assistance and Mrs L. De Sola for secretarial help.

Unusual Endplate Potentials which reflect the Complexity of Muscle Structure

Falk and Fatt1,2 recently proposed a new equivalent circuit to account for the electrical impedance of frog sartorius and crayfish muscle fibres. In this new model (Fig. 1) the transverse impedance of the resting membrane

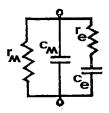

Fig. 1. Drawing of electrically equivalent model for the membrane impedance of frog striated muscle fibre, based on the model suggested by Falk and Fatt¹. If the total transmembrane resistance of the model is to be 500 k Ω (the normal d.c. input resistance of extensor digitorum longus IV fibres), $\tau_m = 500$ k Ω , $\tau_c = 50$ k Ω , $\tau_m = 0.015$ F, $\tau_c = 0.033$ F. The older model³ could result if τ_c were shorted.

is represented by a network of several elements rather than by a resistance and a capacitance in parallel as in the simple rc core conductor cable model3. Falk and Fatt4 have suggested that variations which have been reported in some neuromuscular junctional potentials of crustacean muscle can be attributed to the impedance properties of this more complicated circuit model. The model for frog sartorius muscle is in good agreement with other studies of the structural and electrical properties of the fibres⁵⁻⁸. (A model which differs somewhat from that of Falk and Fatt but is similarly complicated has been proposed for crayfish muscle9.)

While studying frog skeletal muscles which have been treated with certain drugs, I have observed that an endplate current consisting of an early transient component and a continuously declining prolonged component can produce a complex endplate potential which exhibits a minimum between an early transient component and a prolonged component of greater or equal amplitude. Injected currents of similar configuration produce similar complex potentials in the absence of drugs. The correlation of potential with current provides a qualitative demonstration of the complicated nature of the muscle impedance.

 $ar{ ext{S}}$ ingle muscle fibres of extensor digitorum longus $ext{IV}$ (toe muscles) of Rana pipiens were impaled with two micropipettes which were inserted into the endplate region10. Conventional recording equipment was used to detect intracellular endplate potentials (epps) or potential changes which were evoked by injecting current through the second electrode. The injected currents were produced by using a small analogue computer as a voltage source. The motor nerve was electrically stimulated to evoke epps which were reduced in amplitude below the muscle action potential threshold by including in the bath 0.0005 to 0.005 mmolar d-tubocurarine (d-TC) or 0.1 to 2.0 mmolar chemical QX-314 or QX-222. The latter two drugs are, respectively, the triethyl and the trimethyl quaternary ammonium derivatives of the local anaesthetic lidocaine (lignocaine, Xylocaine, Fig. 2). These particular lidocaine derivatives modify the time course and the amplitude of the epp without having any detectable effect on the passive electrical properties of nerve or muscle; they do not act as local anaesthetics at concentrations below 5 mmolar, although lidocaine itself does so at concentrations below 1 mmolar11,12.

In comparison with an epp of like amplitude which was recorded during treatment with d-TC, epps recorded during treatment with drugs QX-314 or QX-222 are of altered waveform. The epp always has a time of rise

to an early peak which is briefer than usual, and a rapid early fall. During treatment with drug QX-222, there is also a prolonged component which typically exceeds the early peak in amplitude, and the resulting epp shows a minimum (Fig. 2B). During treatment with drug QX-314, the prolonged component is not present, and the entire epp is briefer than usual (Fig. 2C).

The time course of the endplate current (epc) which is associated with endplate potentials such as those in Fig. 2 was determined by a modification of the method of voltage clamping used by Takeuchi and Takeuchi¹³. The epc during treatment with drug QX-314 was of brief duration (rise time 0·3 to 0·6 msec, half time of fall 0.2 to 0.5 msec). The epc during treatment with drug QX-222 had a similar earlier transient, but also had a prolonged monotonically decaying residual component of maximum amplitude 0.1 to 0.25 of the brief transient, and half time of decay 20 to 50 msec. The epcs never showed a minimum between early transient and prolonged component, even in cases where the epc did show a minimum (for example, Fig. 2B).

Monophasic currents of form similar to those recorded during treatment with drugs, when injected into a muscle fibre through a second micropipette, could produce the full range of potential changes which are observed during

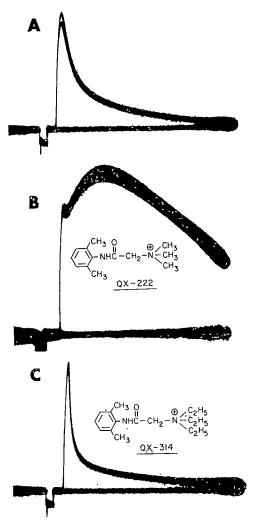

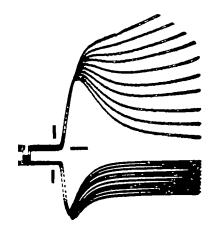

Fig. 2. Endplate potentials recorded from a single fibre of extensor digitorum longus IV during treatment (A) with 0.004 mmolar d-TC; (B) with 0.8 mmolar QX-222; (C) with 0.34 mmolar QX-314. Each trace is a photographic composite of at least three successive epps. The changes in waveform produced by the drugs were completely reversible. Resting potential: -86 mV. Temperature, about 24° C. Ringer solution: 111-3 mmolar sodium chloride, 2·1 mmolar potassium chloride, 2·0 mmolar patassium chloride, 2·0 mmolar calcium chloride, buffered to pH 6·8 with 10 mmolar glycylglycine-piperazine. Calibration pulses (on traces): 1 mV, 1 msec.

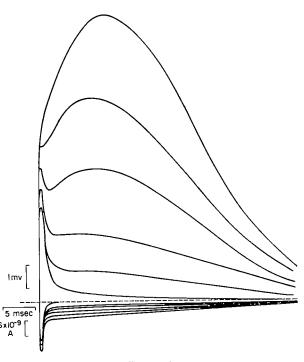

Fig. 3. Response of extensor digitorum longus IV fibre to a transmembrane current. Upper: the waveforms of potential (upper traces) were produced by the transmembrane currents shown in the lower traces. To produce the series shown, the amplitude of the prolonged component of current was gradually increased. Lower: tracings from a similar experiment, showing the range of potentials produced by the currents below the dotted line baseline. The rising phase of the waveforms is not accurately drawn. It is clear that currents which decline monotonically after an early translent can produce potentials that have aminimum. Both series were produced in the absence of nerve stimulation or chemical treatment; similar results could be obtained with pipettes inserted anywhere in the musclefbre. Resting potential: about -84mV in both preparations. Calibrations: upper series, 2 mV, 1 msec, 5 × 10-6 amp. Lower traces as shown.

drug treatment (Fig. 3). The presence or absence of drugs during such experiments with injected currents did not change the potential which was recorded, showing that the relevant effect of the drugs is to change the time course of the epc.

The observation that currents which decline monotonically after an early peak can produce potential changes which have two maxima of roughly equal amplitude can be understood in terms of the model of muscle membrane impedance which was proposed by Falk and Fatt^{1,2}. The rapid decay of potential which can be observed after a current lasting less than 2 msec (Figs. 2C and 3) primarily reflects the re-distribution of charge from c_m to c_e through r_e (Fig. 1). The continued rise of potential during the falling phase of a prolonged current from 2 up to 20 msec after its beginning (Fig. 3) reflects the continued charging of c_m and c_e effectively in parallel with r_m . Qualitatively similar phenomena do occur in a simple rc cable (with transverse elements resulting from r_e in Fig. 1 being shortcircuited13,14), for the capacity of parts of the membrane distant from the point where current is injected has to be charged up through the longitudinal conductance of the core. This effect is, however, much less pronounced than that which is caused by the presence of a resistance as represented by r_o in Fig. 1, and calculations have shown that currents similar to those shown in Fig. 3, when injected into a simple rc cable, give rise to potential changes which do not show a minimum. For the normal epp (including that recorded during treatment with d-TC) which is generated by a current of 2 to 4 msec duration, the complicated nature of the muscle impedance is not evident when potential change is correlated with current. During treatment with drugs QX-314 or QX-222, the endplate current has an early brief component, and, in the latter case, a prolonged component. In such cases it becomes necessary to adopt a more realistic model of the muscle impedance to explain the endplate potentials which were observed.

The relations noted in this study between current. both physiological and artificially produced, and the potential change produced across the muscle fibre membrane do not extend the elegant experiments of Falk and Fatt, but do provide a simple qualitative demonstration of the complexity of muscle impedance. indicate that it is necessary to adopt a realistic view of the impedance of the muscle fibre membrane in any studies of drugs which change the time course of the epc (refs. 16 and 17).

Depressing Effect of Methamphetamine on Self-stimulation in the Cat

It has been shown that the lateral hypothalamus is involved in the feeding response and also in the rewarding reaction to certain stimuli¹. This suggests that amphetamine, an anorexic agent, should depress the self-stimulation of the lateral hypothalamus. Several investigators, using the variable interval as a reinforcement schedule. have, however, reported that the amphetamines, at relatively small doses, had facilitating effects—that is, they caused an increase in response and a lowering of the threshold². In contrast to these observations, the present study shows that methamphetamine, in appropriate doses which depress food and water intake, decreased the rate of response and elevated the threshold for self-stimulation of the lateral hypothalamus.

Bipolar, enamelled stainless-steel wire electrodes were implanted in the lateral hypothalamus in cats (two pairs in each animal). Two weeks after the operation, each animal was stimulated through the electrodes in a behaviour-observation cage. Stimulus-bound feeding responses3 were obtained in seven out of twenty-eight cats. These seven animals were tested for self-stimulation in a modified Skinner box. In this experiment, every bar-pressing was reinforced by intracranial stimulation; a 0.2 sec train of 100 p.p.s., 1 msec pulse from a square wave generator.

Table 1. THRESHOLDS FOR FEEDING BEHAVIOUR AND REWARD, AND RATES OF SELF-STIMULATION BY THE OPTIMAL CURRENTS

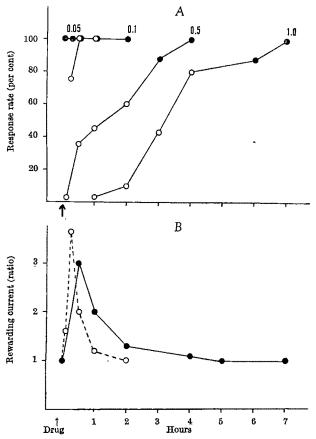

in

High rates of self-stimulation were obtained in all seven cats when they were deprived of food for 24 h. Table 1 shows the threshold currents for reward, rates of barpressing by the optimal currents and the thresholds for feeding responses. In six out of seven cats the optimal currents for self-stimulation were lower than the threshold currents for feeding responses. In the self-stimulation experiment, the currents which were strong enough to elicit feeding responses usually induced forced motor movements such as "sniffing" or "searching", but this behaviour did not prevent the cat from continuous bar-pressing.

Small doses of methamphetamine (0.01-0.05 mg/kg, intravenously) had no apparent effects on normal feeding behaviour, while doses larger than 0.1 mg/kg temporarily inhibited the food intake of the animal. Doses of more than 2.0 mg/kg were apparently an overdose for this experiment because the animals showed immobility accompanied by piloerection and pupil dilatation. These results show that the dose should be lower than 2.0 mg/kg to observe the intrinsic effect of methamphetamine. Accordingly, methamphetamine hydrochloride in doses of 0.05-1.0 mg/kg was twice administered intravenously in random order and at least I week was allowed before another injection.

Fig. 1A shows dose-response relation in seven animals. Methamphetamine of 0.05 mg/kg had no effect and 0.1 mg/kg decreased the rate of response to 76 per cent of the control during 5-15 min after injection, while doses of 0.5-1.0 mg/kg markedly depressed the rate of barpressing. It was repeatedly observed that some animals kept the foreleg on the lever for a few seconds while others reached for the lever with apparent hesitation. As mentioned before, these depressing effects were not caused by overdose or overstimulation, because neither increase in locomotive activity nor ataxia with pupil dilatation was observed.

The effects of the drug on the threshold for self-stimulation were observed by adjusting the stimulus current to a level which barely maintained a stable rate of barpressing response (compare Table 1). Soon after injection of methamphetamine 0.5-1.0 mg/kg, bar-pressing became

irregular and current was manually adjusted to maintain a stable response rate. These experiments showed that methamphetamine elevated the threshold for self-stimulation by two or three times during 15-75 min after injection. This depressing effect was further confirmed by results obtained by the administration of L-DOPA. It has been reported that the central action of the amphetamines is mediated through the catecholamines4. This suggests that the catecholamines should have a similar effect to methamphetamine on self-stimulation. To explore this possibility, L-DOPA, which crosses the blood-brain barrier readily, has been used intravenously at doses of 5-10 mg/kg, which were able to antagonize the effects of reserpine, 0.1 mg/kg, subcutaneously, that is, cats which had been sedated by reserpine were awakened by injection of L-DOPA. At these doses the effect of L-DOPA was to raise the threshold for self-stimulation which was similar to the effect produced by methamphetamine. The duration of the effect was, however, relatively short, probably because of rapid metabolism by monoamine oxidase. A typical result is shown in Fig. 1B and it supports the conclusion on the action of methamphetamine.

Why then was facilitation observed in the experiments of Stein and other investigators? The different results obtained in this and earlier studies seem to be the result of the reinforcement schedule. Dews and Morse⁵ have pointed out that the effect of amphetamine on behaviour is influenced by the control or the predrug rate of response. As mentioned before, Stein and others² have used the variable or fixed interval schedules which strongly inhibited the output of behaviour. Using these schedules the amphetamines could have acted to increase the rate of response even when reinforcement was food or water. The facilitating effects observed in earlier studies could therefore have been the result of depression by the experimental schedules, that is, amphetamine merely released the animal from the inhibition which was imposed by the reinforcement schedule. If this is so, the facilitating effects of amphetamine on behaviour were not necessarily the result of the effects of the agent on the lateral hypothalamus. It should be pointed out that in the earlier experiments² drugs were effective at relatively small doses which were not enough to inhibit the normal feeding behaviour.

The present study shows that, under the continuous reinforcement schedule, methamphetamine in doses which depress normal feeding responses also depresses the selfstimulation of the lateral hypothalamus. This leads to the conclusion that methamphetamine has depressing effects on the mechanism which is involved in the feeding and rewarding reaction in the lateral hypothalamus.

We thank H. Sato and S. Naito for their valuable assistance.

Binding of Cortisol to Human Albumin

An investigation of the binding of cortisol to human plasma proteins led us to re-examine the interaction between cortisol and pure human albumin. Previous workers1-3 have obtained widely differing results for the percentage of cortisol which was bound by a given concentration of albumin, and Brunkhorst and Hess4 have suggested that the number of available binding sites/mole of albumin increases as the albumin solution is diluted. Our results confirm the quantitative findings of Chen et al.3 and suggest that some of the discrepancies in this field may be the result of experimental artefact.

Albumin was obtained from Calbiochem as recrystallized human albumin grade B. It was seen to consist of only one immunological component when reacted in immunoelectrophoresis against anti-human serum (Burroughs Wellcome). Albumin solutions were prepared in 0.07 molar phosphate buffer, pH 7.4, and were then standardized by micro-Kjeldahl estimations using a factor for protein nitrogen of 6.4 (ref. 5). Paper chromatography of 1,3-3H-cortisol obtained from Amersham showed that it was 98 per cent pure.

Samples of cortisol which had been treated with ethanol were taken to dryness under nitrogen; albumin solution was added and the mixture was incubated for 30 min at 37° C. Complete solution was shown by radioactive counting. The concentrations of cortisol which were employed ranged from 0-4 to 400 μ g/100 ml. Ultrafiltration was carried out through 8/32 'Visking' tubing under 4 atm. pressure at 37° C (ref. 6). Within 30 min, five sequential samples of ultrafiltrate of 0.5 ml. volume were obtained from each 5 ml. of albumin solution. percentage of ultrafiltered cortisol was derived from liquid scintillation counting of the original albumin solution and the ultrafiltrate. Loss of cortisol by adsorption onto the sac was noted with aqueous solutions and to a lesser extent with albumin solutions. A plateau value for ultrafiltered cortisol was always reached by the fourth 0.5 ml. sample and this value was accepted as representative of the true level of cortisol in free solution within the sac. We were unable to eliminate the adsorptive loss by any prewashing of the 'Visking' tubing in water or ethanol at room temperature or at 60° C.

Contrary to the expectation of some workers1,7 have found that ultrafiltration of up to 70 per cent of the sac volume does not disturb the initial equilibrium position between bound and free cortisol either in albumin solutions or in plasma, and this finding is in accord with mathematical considerations based on mass action theory8.

A 3.2 per cent solution of albumin which was loaded with cortisol at concentrations of 0.4, 20 and 400 μg/100 ml. gave plateau values for percentage of free cortisol of 38, 39 and 39, respectively. The apparently enhanced binding of cortisol to albumin at low concentrations of cortisol which was noted by some workers4 was not found. This might be the result of adsorptive loss or contamination of albumin with transcortin. The fixed percentage of binding over a wide range of concentrations of cortisol conforms to the hypothesis that albumin has a very large binding capacity for cortisol. In these circumstances, it can be shown1 that the ratio of bound to free cortisol will vary linearly with the albumin concentration, provided that the number of binding sites/mole of albumin remains constant. A relationship of this type has been shown for salicylate binding to albumin. Results obtained with a cortisol concentration of 375 µg/100 ml. and albumin concentrations ranging from 0.01 per cent to 3.2 per cent are shown in Fig. 1 (line A). Line B represents the result which is obtained if the first aliquots of ultrafiltrate are used. The upward displacement of the line could represent increased avidity for cortisol at low albumin con-centrations but is in fact entirely the result of adsorptive

Keller et al.7 noted a decrease in binding of cortisol to rat plasma in the presence of ethanol, and we have confirmed this observation using albumin solutions and human plasma. Additions of 1 per cent and 3.5 per cent ethanol to 3.2 per cent albumin increased the percentage of free

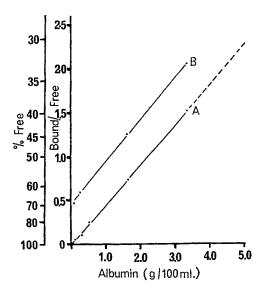

Fig. 1. Relationship between concentration of albumin and binding of cortisol at a total cortisol concentration of 375 μ g/100 ml.

cortisol from 39 per cent to 41 per cent and 50 per cent, respectively.

Extrapolation of line A to 5 per cent albumin suggests that 30 per cent of cortisol would be free and this agrees closely with the value of 31 per cent free found by Chen et al. at this albumin concentration. We have failed to demonstrate enhanced binding by low concentrations of albumin. The variety of results that have been obtained for cortisol-albumin interaction may be a consequence of albumin impurity, use of ethanol as a vehicle for cortisol or adsorptive loss onto semipermeable membrane.

We thank Dr G. K. McGowan for his encouragement.

Estimation of the Respiratory Rate of Young Plaice (Pleuronectes' platessa L.) in Natural Conditions using Zinc-65

THE dynamics of a population of 0 group plaice (that is, fish less than 1 year old) which live near the low water mark is being studied as part of an investigation of food chains on a sandy beach in Loch Ewe, Wester Ross. In this work, it is of prime importance that the respiratory rate of the fish in the sea be estimated, because the energy used for metabolism cannot be calculated unless this rate is known. Until recently it has been impossible to measure the respiratory rate of a fish in its natural environment. Mishima and Odum¹ have suggested, however, that the isotope zinc-65 may be used to measure this rate. These workers found that the elimination rate of zinc-65 from the body of the molluse Littorina irrorata was related to the air temperature and to the body size of the animals, and they suggested that the isotope might be used to study the respiratory rate of the animal in its natural environment.

In the present study, plaice varying in length from 2 to 10 cm were used. Experiments were performed to measure simultaneously the respiratory rate and the elimination rate of zine-65 by plaice which were kept at different temperatures and different feeding levels. The fish were given tracer doses of isotope by introduction of zinc-65 chloride into the water containing the fish. After 48 h the fish were removed and washed, and were then placed in fresh sea water. Whole body counts were made in a Panax scintillation counter, type ZM 28, containing a 1 in. × 1.5 in. sodium iodide crystal, situated 0.25 in. away from the counting tray. The respiratory rate of the fish was measured in a closed system respirometer incorporating a Beckman oxygen electrode, model 777.

The pattern of elimination of the isotope from a group of six plaice held at 16° C is shown in Fig. 1, where all counts have been corrected for decay of the isotope. The fish

	7.00		,,

were fed at maintenance level during the experiment, and had a mean respiratory rate of 0.37 cc of oxygen/g live weight/h. There was an initial rapid loss up to the fifth day, followed by a slower loss from day 5 to day 43, after which time the isotope became stabilized within the body. Within the limits of accuracy of these results, a linear relation for the period day 5 to day 43 seems adequate. Similar observations on the elimination rate of isotopes from the body have been observed by Hoss² using cerium-144 in flounders and by Graham and Telle³ using zinc-65 in rabbits.

The mechanism by which the zinc-65 is eliminated from the body has not been determined in the present case. Estimates were made of the amount of activity in different tissues in the body, 5 days after removal from the isotope. It was then observed that the stomach and intestine had the highest activities, followed by skin, skeleton, muscle, liver, kidney and blood in approximately that order. Certain enzymes, for example, carbonic anhydrase, glutamic dehydrogenase, and the carboxypeptidase enzymes of the intestine, are known to contain zinc.

To obtain a range of respiratory and zinc-65 elimination rates, groups of five-ten plaice of similar sizes were kept at different temperatures: some groups were starved and others were fed. The elimination rate of the isotope was measured from day 7 onwards, and some of the graphs thus obtained are shown in Fig. 2. It will be seen that as the respiratory rate increases, so also does the elimination rate of the isotope. The number of counts/min of each fish during day 7 was considered to be 100 per cent, and further measurements were expressed as a percentage of this. Because in most cases the results for the period day 7-day 17 appeared linear, they were used as the standard for comparison with respiration. A summary of the results so obtained is given in Table 1. In Fig. 3, the percentage of the isotope eliminated in this period has

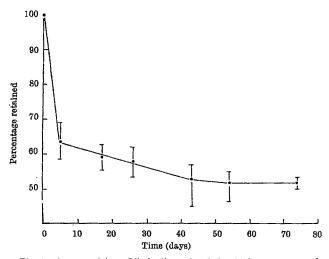

Fig. 1. 0 group plate. Elimination rate of zinc-65 from six fish at 16° C. Vertical ranges indicate extremes of individual variation.

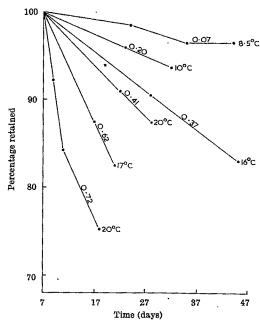

Fig. 2. 0 group plaice. Elimination rate of zinc-65 from 7 days onwards at different respiratory rates. Temperature and oxygen consumption as cc/g/h are given on graphs.

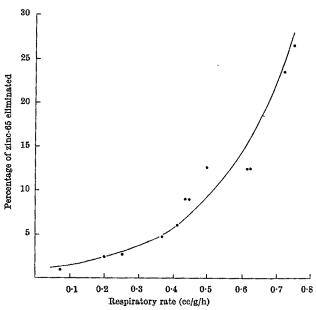

Fig. 3. 0 group plaice. Relationship of zinc-65 eliminated in the period day 7-day 17 with respiratory rate. $Y=0.9337e^{4-8563}X$; standard error of exponent= ± 0.1258 .

been plotted against the respiratory rate; this gives a relation which seems to be independent of temperature.

After this relationship had been established for fish which were confined in containers in the laboratory, the elimination rate of the isotope in place held in a large outdoor tank and in netting tanks on the sea bed was measured. The fish which were used in these experiments were individually marked by subcutaneous injections of coloured liquid latex as described by Riley⁴.

In the first experiment a concrete tank measuring 9 ft. \times 3 ft. \times 3 ft. was connected to a pumped sea water supply and the bottom was covered with sand from the spring tide low water mark. This sand was obtained from the natural habitat of the 0 group plaice, and the fish were fed on animals which were in and above the sand. Twelve 0 group plaice varying in length from 7 to 10 cm were put

into the tank and were fed daily on chopped mussels. The mean quantity of isotope eliminated in the period day 7-day 17 was 8.0 per cent, the pattern of elimination being similar to that in Fig. 1. The mean water temperature was 12.5° C. In the second experiment, sixty plaice varying in length from 3.2 to 5.9 cm were placed in two netting tanks on the sea bed in Loch Ewe, just below the low water spring tide mark. These tanks, which were 12 ft. \times 6 ft. \times 1 ft. high, were made of nylon mesh 5 mm thick, held in a metal frame as described by Steele⁵. The tanks had previously been filled to a depth of 3 in. with sand from the spring tide low water mark. The mean quantity of isotope eliminated in the period day 7-day 17 was 18.25 per cent, the mean water temperature being 14° C. In Fig. 3, a respiratory rate of 0.47 cc/g/h (95 per cent limits 0.45-0.50) is indicated for the first experiment and of 0.65 cc/g/h (95 per cent limits 0.62-0.70) is indicated for the second experiment.

A "standard" respiratory rate for fish has been defined (Fry and Hart⁶) as that obtained from fish which had been fed up until 24 h before measurement and at rest during the period of measurement. In the first experiment, resting plaice of this size had a "standard" respiratory rate of 0.20 cc/g/h at 12.5° C and in the second experiment 0.32 cc/g/h at 14° C. Thus the fish in the first experiment had a respiratory rate of 2.35 times, and the fish in the second experiment a rate of 2.03 times the "standard" rate.

This extra metabolic activity must be attributed to movement in these tanks. In the laboratory experiments where fish were kept in small containers, it was not possible to obtain comparisons of the rate of elimination of zinc-65 and the respiratory rate of actively moving fish over long periods. In short term respiration experiments, however, rates of three-four times the "standard" rate were obtained for actively swimming fish. Thus the respiratory rates of the fish in the tanks lie within the scope of activity measured for 0 group plaice in the laboratory.

The value of 2.03 times the "standard" rate which was obtained in fairly natural conditions is very close to the value of two proposed by Winberg' and provides a basis for calculating the metabolic requirements of the natural population of 0 group plaice in Loch Ewe. Variations in the environment, however, particularly in quantity and quality of food, could affect this value, and it is hoped to undertake more detailed studies to test this method.

Effect on Brain Enzyme and Behaviour in the Rat of Visual Pattern Restriction in Early Life

SEVERAL studies have shown that certain behavioural and biochemical changes can be produced in rats if they are raised in an "enriched environment" or subjected to stress or handling during infancy. Typically, an enriched environment is created by placing some small objects or mates in the cage of the animal or by handling the animal every day for a specified period of time. All these manipulations require an extended period of physical contact either with other animals, with the experimenter or with

both. When animals are handled or permitted to live together, the resulting temperature differential alone can produce physiological changes2, so it is not clear whether some behavioural or physiological changes can be produced in an adult animal by manipulating just the visual or auditory environment in infancy. By eliminating group living and handling, and manipulating only the visual complexity of the environment in which rats were raised, we found significant differences in body weight, brain cholinesterase (ChE) activity and sensory conditioning.

Nineteen litter-mate female Holtzman albino rats, weaned at 30 days of age and matched for body weight, were randomly assigned to either a visual pattern (VP) or a restricted visual pattern (RVP) group. The visual environment of both groups was restricted by a wooden enclosure extending 30.48 cm beyond the front of the cage. The enclosure of the VP group had alternate black and white stripes painted on it, while the enclosure of the RVP group was painted flat white. Each animal was placed in an individual wire mesh cage and remained in its experimental environment, and was supplied with unlimited food and water until it was 90 days of age. The overhead fluorescent illumination diffused light evenly over all cages and a 12 h light-dark cycle was maintained. The animals were never touched nor were their cages removed throughout the experimental period except when the animals were weighed and rated for emotionality3 at 60 days of age. The original experiment which contained only seven rats (four in the VP and three in the RVP group) was replicated with twelve rats (six in each group). Because the trend of behavioural tests and weight gain was identical for original and replicated experiments, all the data have been pooled.

At 90 days of age all animals were weighed and rated for emotionality a second time. The animals did not differ in emotionality rating either when 60 or 90 days old. The VP group, however, gained significantly more body weight than did the RVP group at both 60 and 90 days of age. As evident from Table 1, the VP group also maintained its higher weight gains than the RVP group at 101 days of age when final body weights were obtained.

		ľ	able 1

Difference	27.4	0.1	6.5*	13.5*	23.7*

* Significant at 0.05 level.

Mean body weights for restricted visual pattern group (RVP) and visual pattern group (VP) for the four weighing periods.

We also tested all animals for spontaneous activity in a photoelectric activity cage for 12 h each day for three consecutive days, but within-group variability was excessive and the differences in activity were not significant. Finally, we tested all animals for sensory reinforcement for 7 days, at the conclusion of which the animals were killed and their brains were removed for measurement of ChE activity.

The sensory reinforcement test consists of conditioning an animal to perform a specific task, usually touching a lever, when the only reward is a flash of light in a lightproof chamber in which the animal is working4. We used a sound- and light-proof chamber (28.57 cm × 19.68 cm × 23.49 cm) which contained a stationary lever on one side, 8.89 cm above the floor. The lever was connected to a contact relay which, when touched, could activate a flash of light (6 W) for 0.75 sec in the box and a counter. Each animal was placed for 25 min daily for 7 consecutive days and the number of times the lever was touched was recorded. For the first 3 (adaptation) and last 3 (extinction) days, touching the lever did not activate the light in the box, but the number of touches was recorded. On the 2 days of conditioning, however, the flash of light accompanied each touch of the lever. There were no

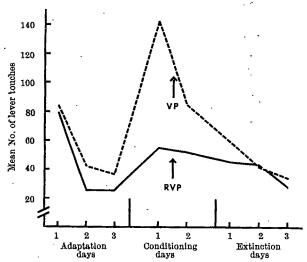

Fig. 1. Mean number of touches by visual pattern (VP) and restricted visual pattern (RVP) groups on sensory reinforcement test. The light flashes were contingent on the lever touching only on conditioning days.

significant differences between the groups on adaptation and extinction days, but the VP group made significantly more responses than the RVP group (P=0.05) on the

days of conditioning (Fig. 1).

Measures of brain ChE activity were obtained for only the twelve animals which were used in the replication. Animals were decapitated and their brains were removed. The brains were weighed and cut into equal anterior and posterior halves. For each half, the cortical (lateral, ventral and dorsal) and subcortical tissues were divided. The four samples thus obtained for each rat (anterior cortex, posterior cortex, anterior subcortex and posterior subcortex) were individually weighed and frozen in dry All samples were then coded so that the analyst could determine whether the tissue was cortical or subcortical, but he was unaware from which group the tissue was taken. The ChE activity was determined by the rate of hydrolysis of acetylcholine perchlorate (ACh). The procedure employed was identical to that of Rosenzweig, Krech and Bennett⁵.

	•	Table 2		
Rearing condition	ChE activity*	Anterior cortex	Posterior cortex	Total cortex

RVP	Mean M	38·67† 5·11	27·33 ‡ 6·06	33·00 ‡ 4·02
Difference		16.33 †	28.47	20·00 ±

All ChE values are in moles ACh × 10¹⁰ hydrolysed/min/mg of tissue.
 † Significant at 0.05 level.
 † Significant at 0.01 level.

The ChE activity for restricted visual pattern group (RVP) and visual pattern group (VP).

Because the subcortical ChE activity between VP and RVP groups was not significantly different, Table 2 presents the ChE activity for the cortical tissue samples only. The posterior cortex sample, which contained the visual cortex, showed significantly greater ChE activity for the VP group than for the RVP group. The ChE activity between anterior and posterior cortical samples within a group, either VP or RVP, did not show significant differences. When the total cortex between the groups was compared, however, the ChE activity for the VP group was much higher than that for the RVP group. Our findings are not in agreement with those of Rosenzweig et .al.1; they found decreased ChE activity in the cortex and increased activity in the subcortex of those rats which were raised in an enriched environment. Our brain samples are not strictly comparable with those in their study, however, because our cortical samples contained lateral, .dorsal and ventral portions of cortex, while in their study only the lateral portion of the cortex was used1,

The results of our study strongly suggest that visual pattern restriction or enrichment in early life may be a critical factor in those studies which have shown behavioural, physiological and biochemical changes in the adult animals raised in groups or handled during infancy. The fact that greater body weight and increased ChE activity of brain can be induced by manipulating visual patterns indicates that the nature of visual input in infancy may cause enduring alteration in some basic physiological mechanisms.

This study was supported in part by a research grant from the US National Institute of Mental Health.

Cortical Activity preceding Speech: Semantic Specificity

Reliable, non-random changes in the electrical activity of the human brain, designated "cortical command potentials", have been observed preceding voluntary hand and foot movements1, finger pressing2 and speech3. Command potentials which have been detected to date have shown relatively undifferentiated uniphasic or biphasic waveforms over the contralateral motor area; no specificity with respect to the voluntary activity time-locked to these potentials has been reported.

This communication shows that average command potentials from the human scalp, preceding and timelocked to speech onset, are characteristically different for the spoken letters "T", "O" and "P". This specificity of command potentials prevails over both the right sensori-motor area and the left temporal "speech association" area; characteristic differences have also been noted between the areas.

The EEG of one young adult male (myself) was measured with bipolar scalp contact electrodes over the right sensorimotor area (C4 to A2 with ground to A1 in the 10-20 system) and the left temporal "speech association" area (T5 to A1 with ground to A2) and recorded on multichannel magnetic tape in a bandwidth 3 dB down at 3 and 100 c/s. A microphone pickup of spoken words triggered a voice-activated switch* which produced a pulse at the audible onset of each spoken word. This pulse was shaped, delayed by 100 msec and recorded on FM tape together with the amplified, non-filtered microphone voice pickup. In any given experiment, I spoke the designated words fifty times each at a self-paced rate of about once every 2 sec. Fifteen experiments were conducted in all, each on separate days over a 2 month period, using the spoken letters "T", "O" and "P", the numbers "2" and "10" and the words "yes" and "no".

Tape recorded EEG data were filtered 6 dB down at

3 and 20 c/s to eliminate possible movement and muscle

^{*} Exploratory studies with all letters in the alphabet indicated that the spoken letters "T", "O" and "P" showed greatest temporal stability in triggering the Mousseau Scientific Instruments AT-1 voice activated switch.

artefact. The tape was then played backwards into the ND-801 'Enhancetron' digital computer which extracted cortical activity time-locked to the trigger pulse representing the onset of each spoken word. The delay which was introduced when recording permitted, on playback, demonstration of summated EEG and voice activity 525 msec before and 100 msec after the onset of a given word.

before and 100 msec after the onset of a given word.

Results for the spoken letters "T", "O" and "P" on different occasions and from two cortical areas are presented in Fig. 1. Command potentials preceding these spoken letters were stable during several experiments (traces 1-2; 3-4; 5-6; 8-9; 10-11; 12-13); they were different for different spoken letters when recording from the same cortical area (traces 1, 2-3, 4-5, 6; 8, 9-10, 11-12, 13), and were unique in the two cortical areas preceding the same spoken letter (traces 1, 2-8, 9; 3, 4-10, 11; 5, 6-12, 13). The non-filtered microphone pickup of the spoken letters which was averaged by computer indicates the stability of the trigger point (traces 7 and 14). Reliable command potential components occurred as early as 310 msec before voice onset. Command potentials preceding the spoken numbers "2" and "10" and the words "yes" and "no" were not as reliable as those preceding the letters because of less stable triggering of the voice activated switch. These numbers and words, however, also seem to show specificity in their respective command potentials.

Previous work with sub-dural electrodes¹ and low frequency filtering to selectively average high frequency muscle artefact activity³ indicates that command potentials preceding voluntary movement and speech are of cortical origin. Speculation regarding the origin and

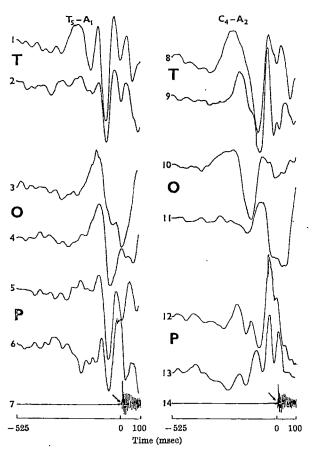

Fig. 1. Average cortical potentials preceding and 100 msec following the spoken onset of the letters "T", "O" and "P" as recorded from the left temporal "speech association" area (75-41) and the right sensori-motor area (C4-A2). Each trace is the average of fifty EEG samples obtained on separate experimental occasions. Arrow indicates point of voice onset.

significance of the specificity of cortical command potentials is undoubtedly premature. Tentatively, it could be suggested that the later pre-voice onset components (latencies up to 200 msec) might correspond to the initiation of pyramidal tract neuronal firing which controls the vocal musculature specific to a particular word while the early pre-voice components (latencies over 200 msec) might be thought of as the electrophysiological signs, associated with the act of selecting and deciding to speak a given word.

Rheology of Microspheres injected into Circulation of Rabbits

A RECENT innovation in the measurement of regional blood flow in animals is the use of radioactively labelled, rigid, inert microspheres of 50μ ($\pm 20\mu$) diameter which are injected into the circulation. The amount of radioactivity in an organ is taken as an index of the number of spheres trapped by the microcirculation of the organ and, thus, of the relative blood flow to that organ.

Determination of the distribution of these spheres in the blood flowing through the larger arteries is useful not only as a check of the validity of the method but also as a source of information about the rheology of mixed suspensions of particles of different characteristics. We have studied the distribution of these microspheres within flowing blood by ultra-rapid freezing of perfused medium-sized arteries in living rabbits. The method for ultra-rapid freezing of the femoral artery of a rabbit in vivo and for subsequent histological processing has been described^{2,3}. With this technique, blood flowing through the segment of artery is immobilized in less than 0.05 sec (ref. 2) and the cross-sections of the artery show an end-on view of the blood as it was when flow was stopped.

In each of two anaesthetized adult rabbits in which the medial branch of the femoral artery (internal diameters 1.0 and 1.1 mm) was exposed and prepared for freezing, approximately 5×10^4 plastic microspheres suspended in 1 ml. of saline containing 'Tween-80' (1:2,000) were injected into the left ventricle of the heart through a catheter passed through the right carotid artery. injection took 5 sec and the femoral arteries were frozen immediately afterwards. In the light microscope, microspheres appeared as semi-transparent amber-coloured disks with no underlying erythrocytes (Fig. 1). (The amber colour may have been the result of the iodine-125 with which this batch of spheres was labelled.) There was seldom more than one sphere in each 8-15µ thick section. Each sphere was surrounded by a layer, two to three cells thick, of closely packed erythrocytes, each with its long axis at a tangent to the curve of the sphere. (This clustering of erythrocytes around the microspheres was not present in a mixture of whole blood and microspheres on a microscopic slide, where there was no flow.) Otherwise, the erythrocyte orientation was the same as in other arteries which were frozen by this technique³. Fig. 2 shows the location of all spheres found in serial sections of one segment of a frozen artery 6 mm long.

The distance from the centre of each sphere to the centre of the vessel was measured with an eyepiece micrometer. This distance was expressed as a fraction of the internal radius of the artery; the artery radius being divided arbitrarily into ten units. A histogram (Fig. 3) was made of the number of microspheres in each of five designated intervals of radial distance. The intervals increased from centre to edge of the artery as a function of the square root so that the specific area of artery described by each interval was equal to each of the others. Thus the number of spheres found in each interval could be compared with the number in any other interval. There was a marked change in microsphere concentration, with a peak concentration at about half the radial distance from the centre of the arteries and a progressive decrease peripherally. These differences in concentration are statistically significant when evaluated by the chi square test (P < 0.001).

The axial accumulation of the microspheres (Fig. 3) was similar to that observed in suspensions of neutrally buoyant spheres flowing through rigid tubes4,5. It resembles more closely the pattern which is observed when the spheres are not prevented from spinning as they flow⁵. The radial variation in the concentration of microspheres extends much further in from the periphery than would be expected from wall exclusion or entrance effect. This suggests that the spheres have been acted on by a force which operates over at least the peripheral half of the vessel radius.

It is likely that the microspheres in the arteries spin in the flowing blood. The sheer across such a relatively large particle in laminar flow would tend to make it spin about an axis parallel to the plane of sheer in laminar flow. Usually, in such arteries, erythrocytes would be oriented with the long axis parallel to the plane of sheer

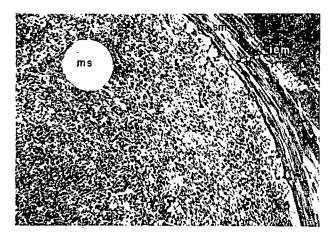

Fig. 1. Photomicrograph of cross-section of ultra-rapidly frozen rabbit femoral artery. Note orientation of erythrocytes around the microsphere. sm, Smooth muscle of arterial wall; iem, internal elastic membrane; ms, microsphere.

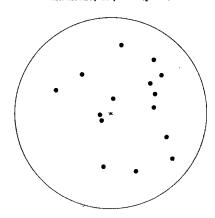

Fig. 2. Map of all microspheres in one segment of frozen artery 6 mm long. * Centre of vessel.

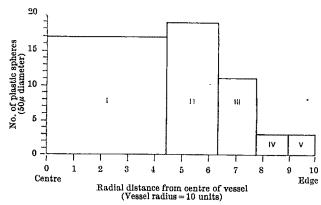

Fig. 3. Itadial distribution of all microspheres found in all segments of both frozen arteries. Cross-sectional area defined by interval I=II=III=IV=V. All three microspheres in area V were touching the edge of the artery.

of laminar flow3. The re-orientation of the erythrocytes immediately surrounding the microspheres suggests a change in the normal pattern of flow, such as would be expected if the microspheres were spinning.

There is no generalized axial accumulation of blood cells in normal blood flowing through such arteries. The only change in the concentration of erythrocytes is a slight decrease at the periphery, which can be attributed to wall effect (entrance effect)3. Concentration of leucocytes tends to increase peripherally, with a peak concentration at one-tenth to two-tenths the radial distance in from the periphery². The distribution of microspheres, which are both larger and more rigid than leucocytes and erythrocytes, shows that axial accumulation of particles can occur in these arteries even though the microspheres must move inward through the crowded mass of erythro-

There was no evident sedimentation of the microspheres, despite the fact that their specific gravity (1.1 to 1.6) was somewhat greater than that of whole blood (1.05). The distribution shown in Fig. 3 suggests that the flow of spheres from such a medium-sized artery into smaller branch arteries is likely to be proportional to the flow of blood into each branch artery.

RADIOBIOLOGY

Body Burdens of Caesium-137 in Toronto in 1964-1967

SINCE 1958 the caesium-137 body burden of persons living in Toronto who have no history of radioactive contamination apart from that present in the normal population has been measured regularly. When the last report was made the burdens of caesium-137 caused by

fall-out appeared to have passed a maximum—the highest average figure recorded was 23.7 nc. in the winter of 1963-64.

Subjects were tested in the University of Toronto steel room². Two groups of between twenty and twenty-five male subjects were the chief source of all data. As far as possible caesium-137 was counted in the same subjects each year.

Table 1. RECENT WHOLE-BODY MEASUREMENTS OF CAESIUM-137

Period of measurements	Average caesium-137 (nc)	Average body potassium (g)	Ratio of caesium-1 potassium (pc./g
Winter 1964-5	21.2	147	144
Summer 1965	18-1	146	125
Winter 1965-6	13.3	143	93
Summer 1966	9.8	137	71
Winter 1966-7	7.3	147	50
Summer 1967	6.4	143	45

The most recent figure (summer 1967) for the average body burdens of caesium-137 in the sample subjects is 6.7 nc. Results for the past 3 yr are given in Table 1. Table 1 also gives the average body potassium measured in grams, and the resultant ratio of caesium-137: potassium (pc./g). The present results, expressed as a ratio of caesium: potassium, are plotted in Fig. 1, together with the corresponding results from previous years¹.

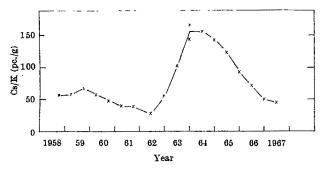

Fig. 1. Average caesium burden of the human body for male adults living in the Toronto area, expressed in relation to the potassium content in the body, as a function of time. The units of measurement are picocuries of caesium-137/g of potassium.

The figure shows that the data for 1963-64 represented a maximum, and that the current levels are approximately those that obtained before the results of the bomb tests of 1961 were noticed. If the data for the period from the winter of 1964-65 until today are approximated by an exponential leading to a constant value of about 30 units, it takes about a year for the caesium burden to be halved, and this is presumably related to the time of residence of fission products in the stratosphere.

Table 2. Comparable figures for body burden for males and females

Period of measurements	Average caesium-137 (nc.)	Average body potassium (g)	Ratio of caesium- 137 : potassium (pc./g)	Range of ratios
Summer 1966				
Males	9.8	137	71	41-148
Females	5.4	97	56	23-98
Autumn 1966				
Males	8.0	146	54	29-99
Females	4.3	94	48	21-80

As part of an epidemiological study of the caesium-137 burden of persons living near sites of future nuclear power stations, measurements were carried out on male and female subjects from one area. Each group consisted of between twenty and thirty subjects. The average caesium-137, potassium and caesium: potassium levels for the men and women are shown in Table 2. These results help to confirm the observed differences in the ratios of caesium: potassium between the sexes.

BIOLOGY

Effect of High Concentration of Carbon Dioxide on the Ionic Composition of Rainbow Trout Blood

Previous work has demonstrated that although moderately high concentrations of free carbon dioxide in the water decrease the ability of fish to extract oxygen from the water 1.2 and to withstand low oxygen concentrations 2. this effect is diminished if the fish become acclimatized to the level of free carbon dioxide which is present 2.4. It is known that acclimatization involves an increase in the alkali reserve of the blood to maintain the pH value at the normal venous level of 7.2 (ref. 5). The experiment reported here was made to determine changes in other ionic components of the blood, as part of a wider programme to investigate the reactions of fish to physical and chemical changes in their environment.

Tests were made with yearling rainbow trout (Salmo giardnerii Richardson) held in aquaria of 40 l. capacity and supplied with a hard de-chlorinated tapwater and aerated with controlled mixtures of air and carbon Concentrations of free carbon dioxide in the water were calculated from the pH value, bicarbonate alkalinity, temperature and total solids, using the monograms of Dye. Temperatures were not controlled and ranged from 12.5° to 16.0° C, with variations of not more than ±1.5° C for any single experiment. Fish were transferred from normal aerated water to the test aquaria and, after a fixed interval, were anaesthetized with MS 222; they were then removed and a sample of cardiac blood was Control fish were used with each experiment. Blood samples from groups of at least three fish were pooled, allowed to clot, centrifuged and the serum was analysed for sodium, bicarbonate (Conway microdiffusion technique?), chloride (EEl chloride meter) and phosphate*. At least two replicates were made for each test condition run with high levels of free carbon dioxide.

Results of the experiments are shown in Fig. 1. With 35 p.p.m. of free carbon dioxide in the water, the bicarbonate in the serum rose from the control level of 6.75 mequiv./l. to 32.2 mequiv./l. within 24 h, and to 39.5 mequiv./l. with 65 p.p.m. of free carbon dioxide; somewhat higher than that given for whole rainbow trout blood by Lloyd and Jordan⁵ of 30.1 mequiv./l. after exposure of trout for 6 days to 50 p.p.m. of free carbon dioxide. The increase in bicarbonate concentration was fairly slow, being only half complete at 6 h, and a roughly corresponding decrease occurred in serum chloride levels, which fell from 152.5 mequiv./l. to 114.6 mequiv./l. after 24 h at a concentration of 35 p.p.m. of free carbon dioxide and 111.0 mequiv./l. with 65 p.p.m. of free carbon dioxide.

Sodium concentrations in the serum did not differ significantly from the controls, neither did the levels of inorganic phosphate (average 12.7 mequiv./l.). change in serum chloride content of fish which were exposed to 35 p.p.m. of free carbon dioxide for 24 h was, however, 13 mequiv./l. greater than the corresponding change in bicarbonate level; the nature of the extra anionic component to compensate for this is not known.

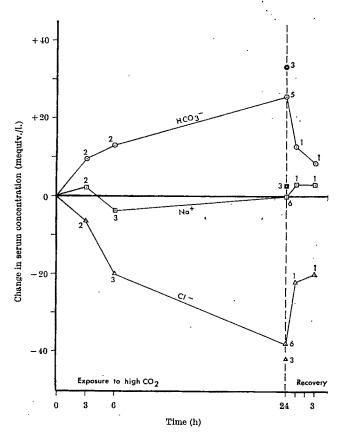

Fig. 1. Change in serum sodium, chloride and bicarbonate concentrations of rainbow trout exposed to high levels of free carbon dioxide. Open symbols: 35 p.p.m. of free CO₂; closed symbols: 65 p.p.m. of free CO₂. Figures against each point are the number of replicate tests made. Control values (mequiv./l.) with standard deviations: sodium 170 ± 5.7 , chloride 152.5 ± 6.8 , bicarbonate 6.75 ± 2.8 .

On removal of the high level of free carbon dioxide from the water, the serum bicarbonate and chloride levels returned towards the normal levels, but the curves tend to flatten out after 1 h. Even after 3 h, the chloride level was still 20.5 mequiv./l. lower, and the bicarbonate 8.7 mequiv./l. greater, than the controls, indicating that some other anionic component or components totalling about 12 mequiv./l. was still present.

A decrease in the concentration of serum chloride has been observed by several authors in salmon (Salmo salar) during the transition from the parr to the smolt stage and has been thought to be an adaptive stage towards a seawards migration because it is accompanied by changes in the activity of the chloride secretory cells of the gills. A decrease in the serum chloride : sodium ratio has been found for adult salmon in sea water10, and the lower chloride levels were thought to be balanced by the formation of an unknown anionic component. The data presented here show that a decrease in the serum chloride: sodium ratio, accompanied by an increase in bicarbonate level and an unknown anionic component, can also result from an environmental stress which is completely unrelated to problems of osmotic adaptation.

Gibberellin from Barley Embryos

In recent years, considerable interest has been shown in the potentialities of the aleurone layer of barley as a site for synthesis of α-amylase in response to added gibberellins^{1,2}. It now seems probable³ that, when barley germinates without additives, an endogenous gibberellin is concerned in the formation of many of the hydrolytic enzymes which degrade the reserves of the endosperm. It was therefore of interest to study the embryo with a view to determining which tissues may be involved in the production of the postulated enzyme-inducing hormone.

On the basis of results of experiments involving excision of various organs from barley embryos, followed by measurement of the rates of cell wall degradation and formation of α -amylase in the endosperm, MacLeod and Palmer4 reported that during germination the axis of the seedling is responsible for the production of a gibberellin-like hormone which controls the synthesis of hydrolytic enzymes in the aleurone. Recently, Radley⁵ has claimed that the scutellum is the organ involved in the production of gibberellins; this claim was based on estimations and tentative identifications of gibberellins which were actually present in the scutellum and the axis of the embryo or secreted from them into agar.

There need be no real conflict, however, between the two sets of observations because, whereas MacLeod and Palmer performed their dissections on grain which had been allowed to imbibe water for 2 h at 25° C (the minimum time of hydration which allows the tissues of the embryo to be manoeuvred), Radley worked with grain which had been previously supplied with water for 18 h. Many events of metabolic importance take place during the first 18 h of imbibition: for example, in Proctor barley, the root has emerged from the coleorhiza (that is, the grain has germinated) and degradation of endospermic reserves has begun4. This observation suggests that a gibberellinlike material had migrated from the embryo to the aleurone layer within 18 h of introducing water to the grain.

With a view to re-examining interactions between axis and scutellum during this 18-h period, either the seedling axis (coleoptile, coleorhiza and the enclosed seedling leaf, node and rootlets) or else the entire embryo (the axis+ scutellum) was removed from six dehusked grains at intervals after these grains had been set to germinate at 25° C

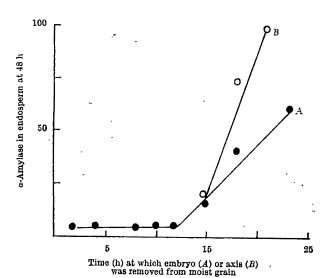

Fig. 1. Development of a-amylase in endosperm of mutilated barley. A, Embryo removed at times shown on the abscissa; B, axis removed, and scutclium left in position, at times shown on the abscissa. Results for A and B were identical up to 12 h. a-Amylase units are according to Briggs*, and are for six grains. Each point is the mean of results of two separate experiments.

on irrigated filter paper, and the mutilated grains were returned to the germination chamber for the remainder of a 48 h period. The endosperms were then assayed for α-amylase activity by the method of Briggs⁶; results of these analyses are shown in Fig. 1.

It is clear that, during the first 12 h of imbibition, no material capable of stimulating formation of α-amylase was released from embryo to aleurone because the separated endosperms (Fig. 1A) showed no evidence of enzyme synthesis during the subsequent incubations of between 36 and 46 h. Nor was there any response to the presence of the scutellum alone, for, when the axis was removed between 2 and 12 h leaving the scutellum to exert its influence independently for the remainder of the incubation period (Fig. 1B), once again no formation of α-amylase could be observed. It thus seems that, for the period covered by the experiment, the scutellum in isolation is incapable of secreting gibberellin-like material to the endosperm.

When the embryo was left in situ for 15 h or longer, subsequent formation of α-amylase in the endosperm took place successfully, and the longer the preliminary association between embryo and endosperm, the greater was the amount of a-amylase formed at 48 h. This is consistent with the observation of Kirsop and Pollock' that a 3 day association of the embryo with its endosperm is needed for maximum development of extract in barley during malting; it is also consistent with the recent demonstration by Chrispeels and Varners that isolated aleurone requires a continuous supply of gibberellic acid to allow continued production of α -amylase.

The amount of a-amylase formed in grains in which the scutellum was left in position was approximately twice as great as in those from which the whole embryo had been removed. This need not imply that the scutellum synthesizing additional gibberellin; because the scutellum functions as an organ of translocation, the extra activity could have resulted from a transient accumulation in the scutellum of gibberellin which was originally derived from the axis.

Although it is clear from the results presented here that the axis of the embryo is intimately involved in initiating the metabolic sequence which culminates in synthesis of α-amylase in the aleurone, it must be emphasized that this does not constitute proof that the axis is the site of gibberellin synthesis, though this is possibly the simplest explanation of the findings. Nor do these results disprove Radley's contention that the scutellum is the site of synthesis of gibberellins after growth of the grain for 18 h. If the scutellum is the organ involved, however, then it would seem that it is initially dependent on the axis for some factor needed for gibberellin production.

Conflicting Measurements of Sodium and Potassium Uptake by Barley Roots

Barley roots have been widely used in studies of ion uptake, but there are conflicting reports about the uptake of sodium and potassium which need some reconciliation.

Some published data show that in 10 mmolar chloride solutions there is little or no selectivity between sodium and potassium. Jackson and Stieff¹ found that uptake from (5 mmolar potassium chloride + 5 mmolar sodium chloride) favoured sodium, but Epstein^{2,3}, using solution containing additional calcium sulphate, found that uptake of tracer from 10 mmolar solutions showed a small preference for potassium (about two-fold). The difference between these two sets of results seems to have been caused by the presence of calcium in Epstein's experiments3.

I have found4 the uptake of potassium to be about six times faster than that of sodium from solutions which contained calcium, and in which the ratio of potassium to sodium was 0.33. This is an eighteen-fold selectivity of potassium; selectivity is defined as:

potassium uptake sodium concentration outside sodium uptake potassium concentration outside

The data in Table I also show this high preference for potassium against sodium because rubidium-86 acts as a tracer for potassium in barley roots2.

Table 1. UPTAKE OF RUBIDIUM-86 AND SODIUM-22 FROM SALT SOLUTIONS*

	Cor	atent ·	Uptake (μ equiv./g/h)

* Solutions for pr	etreat	ment and	d uptake con	tained 0.5 m	molar calcium

sulphate.

There are similar differences in the amounts of sodium in the roots at salt saturation. Jackson and Stieff' found the ratio of potassium to sodium in the roots to be close to that in the solution; I have consistently found ratios in the root about six to ten times that in the solution.

One difference between these results is in the preparation of the tissue. Epstein, and Jackson and Stieff, used roots of seedlings grown on calcium sulphate solutions. Such plants have low contents of potassium and sodium (about 20 µequiv./g fresh weight and 2-4 µequiv./g fresh weight, respectively), because content is restricted to

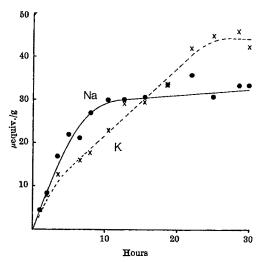

Fig. 1. Time course of sodium and potassium uptake (μ equiv./g) from a solution of 2.5 mmolar potassium chloride + 7.5 mmolar sodium chloride + 0.5 mmolar calcium sulphate. \bullet , Sodium; \times , potassium.

that available from the seed. The roots I used4,5 were from seedlings grown from germination on salt solution with added nutrients. When they were used, the roots seemed to have reached salt saturation for the particular solution in which they were grown, and contained about 70 μequiv./g fresh weight of potassium and 20 μequiv./g of sodium.

Fig. 1 shows the time course of salt uptake as "low roots reach salt saturation. Roots grown on 0.5 mmolar calcium sulphate were transferred to (2.5 mmolar potassium chloride + 7.5 mmolar sodium chloride + 0.5 mmolar calcium sulphate) at the start of the experiment and the salt content of the roots was measured during the next 30 h.

The principal point of interest is the different behaviour of sodium and potassium. Initially there was a rapid uptake of both ions, with a selectivity of about two to three-fold in favour of potassium. At about 10 h the rate of sodium uptake fell to a very low value, but potassium uptake continued and eventually the tissue had taken up more potassium than sodium. There are clearly large changes in selectivity between the early and later stages.

Table 1 compares tracer uptake from solutions labelled with rubidium-86 or sodium-22 by tissue in low and highsalt states, which shows that the decreased uptake of sodium is largely the result of a decrease in sodium influx-not of establishment of a state of flux equilibrium. The decreased influx of sodium occurs in tissue which has been in 10 mmolar potassium chloride as well as in tissue which has been in a solution containing sodium. The influx is therefore related not to the uptake of sodium as such, but to the total salt uptake irrespective of whether it is potassium or sodium (Table 1, lines 2 and 3). This change in selectivity may be related to the decrease in sugar content which takes place during salt uptake (from 60 µmoles/g in low salt to 15 µmoles/g after 24 h in salt solution).

The purpose of this communication is not to discuss the mechanisms involved in the uptake of sodium and potassium, but to make a point about the relation of this work to uptake by whole plants.

The rapid uptake of salt in the first 20 min or so after transfer from calcium sulphate to a salt solution has been shown by Epstein to be related to two different processes, with different selectivity for sodium and potassium. I believe there is a danger in assuming that these measurements represent the behaviour of plant roots growing in soil. The "low salt" roots grown on calcium sulphate solutions are in a state of mineral depletion and I suggest that this state leads to a "forced" uptake of salt in which some aspect of uptake is exaggerated, possibly Epstein's second component.

I do not mean to criticize the authors I have cited. Studies of the initial uptake have been most valuable, but their value will be increased when they can be related to uptake by roots which are nearer salt saturation. The establishment of this relationship is particularly important if attempts are made to interpret uptake of salt by plants growing in natural conditions. In these situations the continual exposure of roots to ions from the soil, even at a low level, may prevent the establishment of conditions during cell development which lead to the large initial uptake of these "low salt" roots.

Effects of Kinetin and Actinomycin D on the Susceptibility of Nicotiana glutinosa L. to Infection by Tobacco Mosaic Virus

KINETIN (6-furfurylaminopurine) is known markedly to influence the rate of synthesis and degradation of plant protein and nucleic acid1. For this reason, its effect on virus infection has been of interest²⁻⁴. Although both increases and decreases in susceptibility have been noted2-4, Soans5 consistently found that when kinetin was applied to leaves of *Nicotiana tabacum* L. cv. "White Burley 'necrotic'", susceptibility to infection with tobacco mosaic virus (TMV) was reduced. Inoculation with TMV 4 days after treatment with kinetin showed reduced numbers, increased size and a delay in the appearance of the local lesions, while mixing kinetin with virus before inoculation produced no significant effects.

We studied the effect of varying the concentration and number of treatments with kinetin on the susceptibility of detached N. glutinosa L. leaves to TMV. Eight leaves from the four mid-positions of 10 week old N. glutinosa seedlings were used as the minimum sample in these experiments. Petioles were dipped through holes in 0.25 in. 'Styrofoam' sheets floated on tap water in an enamelled pan which was almost completely covered with a glass plate. The pan was kept continuously under 'Daylight' fluorescent tubes (700 ft.-candles at leaf level) at 24° C. Kinetin was brought into solution by autoclaving in distilled water for I h at 15 lb./in. and was applied by spreading the solution on the right or left half of the leaf. After 4 days, the entire leaf surface was inoculated with purified TMV (U-1) at 40 µg/ml. to which was added 50 mg of 'Celite'/ml. of inoculum. The half leaf which did not receive kinetin served as a control. Local lesions were counted 4 days after inoculation. 30 p.p.m. of kinetin was the optimum concentration for inhibition by kinetin of susceptibility to infection when applied 4 days before inoculation. This concentration was used in sub-We also demonstrated that insequent experiments. hibition increased with up to three daily applications of kinetin.

Inhibition of virus infection induced by kinetin may be related to its stimulation of host RNA and protein synthesis3. Conversely, inhibitors of host-RNA and protein synthesis might be expected at sufficiently low concentrations to favour infection with RNA virus. Actinomycin D inhibits DNA-dependent RNA synthesis in cells6, so we were interested in whether it could act in this way.

Soans⁵, in some preliminary experiments, had demonstrated that while 25 µg/ml. of actinomycin D when fed through the petioles of detached N. glutinosa leaves was extremely toxic, the leaves tolerated a concentration of 5 μg/ml. Exposures to the latter concentration for 3 h increased susceptibility to infection when leaf blades were then rubbed with TMV, but pretreatment for 8 and 12 h resulted in fewer lesions as compared with the controls.

Actinomycin D was dissolved in distilled water, and the petioles of detached leaves of N. glutinosa were dipped into vials for 2 h in different concentrations of actinomycin. The control leaves were cultured in distilled water. After the appropriate treatment with actinomycin D, the leaves were rinsed and transferred to vials containing distilled water and inoculated with TMV as before. Concentrations of actinomycin D of 2.5, 5.0, 10.0 and 15.0 μ g/ml. produced 148, 134, 92 and 88 per cent, respectively, of lesions in treated leaves as compared with controls. The experiment was repeated three times with similar results. The optimum concentration of 2.5 µg/ml. of actinomycin D was used in subsequent experiments to determine the duration of exposure for maximum stimulatory effect. Pretreatment for 1, 2, 3, 4 and 5 h resulted in a percentage of lesions in treated leaves as compared with controls of 109, 160, 102, 89 and 77, respectively. The increase after exposure for 2 h was significant at the 5 per cent level.

Table 1. EFFECT OF ACTINOMYCIN D ON THE SUSCEPTIBILITY OF Nicotiana

		9700000	W XU XMI		
No	actinomycir	ı D	A	ctinomycin .	D
Kinetin- treated half-leaves	Control (C) halves	Kn/C × 100%	Kinetin- treated half-leaves	Control (C) halves	Kn/C × 100%
1,344	2,498	53	1,416	1,758	81
Each figure	represents l	local lesions	for thirty-two l	alf-leaves.	

To study a possible combined effect of the two substances on susceptibility, 30 p.p.m. of kinetin was applied twice at intervals of 24 h by spreading it on an equal number of right and left half-leaves of thirty-two detached N. glutinosa leaves with their petioles dipping in distilled water in vials. Three days after treatment with kinetin, actinomycin at 2.5 $\mu g/ml$. was applied for 2 h by the method previously described. Sixteen of the leaves used in each experiment received water instead of actinomycin D. The leaves were then inoculated with TMV, and kept under the lights for 4 days, with their petioles dipping in distilled water. Had the effects of actinomycin D and kinetin been independent of one another, then one would expect the ratio of lesions in kinetin-treated half-leaves to those in untreated halves to be unaffected by treatment with actinomycin D. Table 1 shows, however, that the percentage of lesions in half-leaves treated with kinetin as compared with untreated halves was 81 with actinomycin D treatment and 53 without, indicating an interaction between the two substances.

Results similar to ours, showing an inhibitory effect of kinetin on susceptibility to plant viruses, have been reported3,4, although a stimulation has also been described². Actinomycin D has been found to be inhibitory to cellular RNA without reducing TMV-RNA synthesis7,8. This is the first report, however, of the stimulation of susceptibility to infection by actinomycin D (ref. 9).

We measured the initial establishment of infection in these experiments. Establishment of the virus and subsequent replication are distinct phases of the infection process, and are affected in different ways by different treatments10. It is therefore of interest that the compounds we used in this work should affect establishment as one might expect them to influence replication. Our experiments with kinetin and actinomycin D combined suggest some kind of interaction between the two compounds.

This work was supported in part by the US Atomic Energy Commission. We thank Merck, Sharp and Dohme for actinomycin D.

Free Dissolved Enzymes in Lake Waters

THERE has been much discussion about the release of enzymes from living or dead organisms in lake and sca water, and their subsequent participation in chemical transformations¹⁻⁵. There is, however, little and only incomplete evidence of detectable amounts of free enzymes which are still active in bodies of water. In particular, some authors attribute a catalytic role to free dissolved phosphatases in the hydrolysis of phosphate esters by natural waters⁶⁻¹⁰. This communication reports investigations of free phosphatases in the waters of eutrophic lakes, including Pluss-See near Ploen, with special reference to their ecological importance.

The activity of free dissolved alkaline phosphomonoesterases (EC.3.1.3) was directly determined in each sample by a slight modification of an earlier method11, using p-nitrophenylphosphate as the substrate. As soon as possible after collection, 10 ml. of lake water was mixed with an equal volume of 1 molar tris-hydroxymethylaminomethan-hydrochloric acid-buffer, pH 8.4, containing 5×10^{-3} molar magnesium chloride and immediately filtered through a membrane filter ('Göttingen', MF 50, with a maximum pore size of 0.6μ). A sample of the filtrate (2 ml.) was thoroughly mixed in sterile 15 ml. tubes closed by silicon stoppers, and containing 1 ml. of 10-3 molar p-nitrophenylphosphate substrate. After 96 h incubation at 25° C the extinction of p-nitrophenol hydrolysate was measured with a Zeiss 'Elko II' photometer (filter S 42, 418 mu) against distilled water. Each determination required one substrate-buffer blank (1 ml. of substrate solution and 2 ml. of 0.5 molar buffer solution) and one sample-buffer blank (1 ml. of 1 molar buffer solution and 2 ml. of the mixture of lake water and buffer). The mean values of the blanks were subtracted from the standard All determinations were repeated three times. The sterility of the experiments was tested by plating out 0.1 ml. of test solution on 10 ml. of 1.5 per cent Difco nutrient agar in Petri dishes. The amount of p-nitrophenol hydrolysate formed in a minute in 1 ml. of water sample (nmole/ml./min) was taken as the total enzyme activity. Specific enzyme activity was obtained by referring the total activity to the content of protein dissolved in the lake water, which was estimated by the Lowry-Folin reagent method after Povoledo and Gerletti12: 1 ml. of a solution of 10 per cent sodium carbonate in 5 normal sodium hydroxide and 0.3 ml. of a 0.5 per cent aqueous solution of CuSO₄.5H₂O were made up to 15 ml. with filtered lake water. After addition of 1 ml. of Folin's

phenol reagent (Merck) the mixture was kept at 55° C for 45 min and then quickly chilled. Extinction was measured with a Zeiss 'Elko II' photometer using filter S 75. The extent of microbial phosphatase activity was shown by assaying unfiltered water by the same procedure. Other pH dependent phosphomonoesterases, apart from the mentioned phosphomonoesterases, were estimated by use of sodium citrate buffer, pH 3·2-6·4, and glycine-sodium hydroxide buffer, pH 9·0-11·5. Dissolved inorganic o-phosphate was determined by reducing the phosphomolybdate complex with stannochloride. The total dissolved phosphorus was found by treating the water with 1/50 volume of 20 per cent sulphuric acid. The difference between total dissolved phosphorus and inorganic o-phosphate was termed substrate phosphorus.

In the eutrophic lakes which we have studied the maximum activity of free dissolved alkaline phosphomonoesterases amounted to 15 nmoles/ml./min and 2×10^{-6} nmoles/ml./min/mg of protein for the maximum specific value. Considering the complexity of such biotopes this activity is obviously caused by a mixture of diverse isodynamic enzymes of the same or different origin in extremely low concentrations. Analysis of free lake isoenzymes at different pHs, however, showed only two very marked maxima of activity at pH 5.6 and pH 8.7-9.1, respectively (Fig. 1). This means that acid phosphatases had their maximum activity in lake water at pH 5.6, whereas the pH optimum for alkaline phosphatases ranges from pH 8.7 to pH 9.1. In the slightly alkaline lake water, therefore, the complex of free alkaline phosphomonoesterases can probably be considered to be catalytically efficient and therefore of ecological importance. obtain some idea of the enzyme activity of these alkaline phosphomonoesterases we considered that it would be interesting to investigate certain characteristics of these lake water enzymes. About 75 per cent of the enzyme activity was inhibited by treatment for 10 min at 100° C. Temperature investigations indicated optimum activity at 27° C. Examination of the activation energy using the Arrhenius equation in the form $\ln K = (E/R \times T) + \text{constant}$ revealed an activation energy of 16.5 kcal/mole (Fig. 2). The effect of substrate concentration $(X)_0$ on the activity (v) of alkaline lake phosphomonoesterases at pH 9.0 was

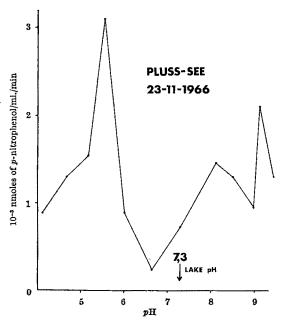

Fig. 1. Effect of $p{\rm H}$ on the activity (10^{-3} nmoles of $p{\rm -nitrophenol/ml/min}$) of free alkaline lake phosphomonoesterases from Pluss-See. The momentary value for the $p{\rm H}$ of the water sample was 7·3. The solutions containing $3\cdot3\times10^{-4}$ moles/l. of $p{\rm -nitrophenylphosphate}$ were buffered with $3\cdot3\times10^{-4}$ moles/l. of sodium citrate ($p{\rm H}$ 3·2-6·4), trishydrochloric, acid ($p{\rm H}$ 7·2-8·5) and glycine-sodium hydroxide ($p{\rm H}$ 9·0-11·5) and were incubated at 27° C.

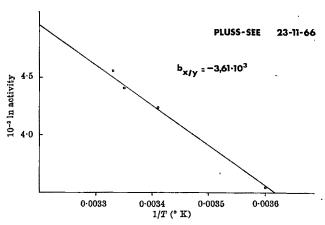

Fig. 2. Estimation of the activation energy of free alkaline lake phosphatases at pH 8·8 buffered with 6·7 × 10⁻⁴ moles/l. of glycine-sodium hydroxide. The logarithm of the activity (10⁻³ moles/ml./min) is plotted against the reciprocals of temperature (°K). Substrate concentration was 3·3 × 10⁻⁴ moles/l. of p-nitrophenylphosphate.

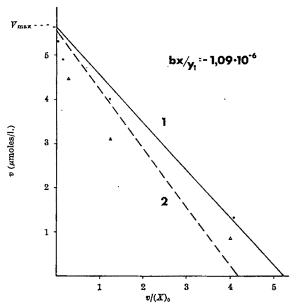

Fig. 3. Relationship between reaction velocity v (μmoles/l. of hydrolysate) and substrate concentration (X)₀ (μmoles/l.) for alkaline lake phosphatases plotted in the graphical transformation of Eadie¹³. Slope 1 (Φ), without inhibitors; slope 2 (Δ), with addition of 3·4 μmoles/l. of sodium orthophosphate. The mixture was incubated in 0·17 moles/l. of glycine-sodium hydroxide buffer, μH 8·9, at 27° C.

investigated using p-nitrophenylphosphate ranging at a concentration of from 3.3×10^{-7} to 3.3×10^{-4} moles/l. Michaelis-Menten constants (Km) were estimated by a graphical transformation after Eadie¹³, using the equation V_{max} V_{o} To correspond with the negative \overline{Km} \overline{Km} $(X)_0$ value of the slope of the best fitted curve the value of Km was calculated as 1.09×10^{-6} moles/l. (Fig. 3). Enzyme activity was not significantly inhibited by orthophosphate up to the maximum concentration found in lake water $(3.4 \mu \text{moles/l.}; 319.6 \mu \text{g P(PO_4)/l.})$. Sodium sulphide (20 mg/l.), however, competitively inhibited enzyme activity significantly (t test) by increasing the value of Km approximately six-fold. Substrate constants of the lake enzymes were rather small compared with the Kmdata of alkaline phosphomonoesterases studied in some species of blue-green algae from the same lake. example, the Km of the alkaline phosphomonoesterases of Oscillatoria rubescens Gomont and Pseudanabaena galeata Böcher ranged from 5×10^{-4} moles/l. to $5\cdot 4\times 10^{-5}$ moles/l. The activity of the phosphatases of blue-green algae was competitively inhibited, in contrast to the lake

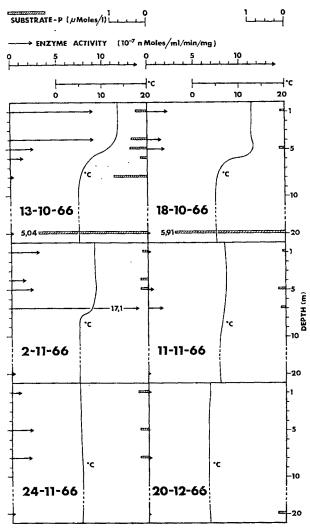

Fig. 4. Temporary variations in the specific activities of alkaline p-nitrophenyiphosphate phosphomonoesterases (10^{-7} nmoles/ml/min/mg of protein) in Pluss-See (strows) plotted against the thermcolines and the content of substrate phosphorus (μ moles/l. columns).

enzymes, by 3.1 µmoles/l. of orthophosphate. In lake water, however, optimal conditions for enzyme activity do not usually exist. Thus the alkaline phosphatases of the Pluss-See were shown to be less active (43 per cent) in the lake compared with the experimental data obtained for optimal pH and temperature conditions. The enzymes lost half of their activity after exposure for 3.2 days at 18° C.

The concentration of free enzymes in lake water is apparently correlated with the amounts of phytoplankton and bacteria. In Table 1 the activity (b) of dissolved phosphomonoesterases of filtered lake water is compared with the total activity of unfiltered water (a). In the chief zone of destruction of phytoplankton (4-5 m deep) mineralization is obviously coupled with a sudden release of enzymes, indicated by a striking decrease of the quotient a/b. At other depths this quotient had a medium value. Total and specific activities of lake phosphatases are almost exclusively restricted to the epilimnion rich in phytoplankton (chief phytoplankton of the Pluss-See are Oscillatoria agardhii Gomont, O. redekei van Goor and

Table 1. HYDROLYSIS OF p-NITROPHENYLPHOSPHATE AT DIFFERENT DEPTHS

Polystyrene Replicas for Scanning Reflexion Electron Microscopy

THE preparation of biological material for examination in the scanning reflexion electron microscope frequently involves coating the specimen with evaporated metal. With a small, conventional vacuum coating unit it is often difficult to achieve an adequate coating without damaging the specimen by radiation from the metal source. The technique of Lingappa and Lockwood¹ which has been used in this laboratory for the observation, by light microscopy, of mycelia and stomata, has been modified and successfully applied to overcome this problem.

A solution was made of 10 per cent commercial, expanded polystyrene in a mixture of two parts benzene and one part toluene, and a small quantity was placed on the surface of a leaf. When the solvent had evaporated, the

Fig. 1. Scanning reflexion electron micrograph of a polystyrene replica of a salt gland of Limonium vulgare. (×1,180)

thin film of polystyrene was removed and placed under a microscope so that areas of interest could be selected. Pieces of the replica were fixed with 'Durofix' to a specimen holder and coated with gold-palladium in a vacuum coating unit before being examined in the 'Stereoscan' microscope.

A preliminary investigation shows that quite fine detail can be resolved from the replica, as seen in the accompanying micrograph of part of the leaf surface of *Limonium*

vulgare.

I thank the Cambridge Instrument Company Limited for the use of their 'Stereoscan' microscope, and Dr B. Shachar of this department for the use of the micrograph which forms part of a current project on *Limonium*.

GENETICS

Genetic Load of an Evolutionary Change

According to Fisher's "Fundamental Theorem of Natural Selection", the rate of change of the mean fitness of a population equals the genetic variance in fitness. If w is the fitness and $V_{\rm Gw}$ the genetic variance in fitness, then by Fisher's theorem

$$\Delta \widetilde{w} = V_{GW}$$

Falconer² showed that if fitness varies in a way that is partially determined by variations in a character, x, then

$$\Delta \bar{x} = cov_{G}(x, w)$$

where $cov_G(x,w)$ is the genetic covariance of x and w. This equation Falconer calls the "Extension to Fisher's Fundamental Theorem". It will be true only if the regression of fitness and the character is linear. That is, we must have a relationship

w = a + bx

where

$$b = \frac{cov_{\rm G}(x,w)}{V_{\rm Gx}}$$

It then follows that the genetic load of any change $\Delta \bar{x}$ in the mean of the character can be calculated. We have by definition of the genetic load³

$$L = \frac{w_{\max} - \overline{w}}{w_{\max}}$$

where w_{max} is the fitness of the most fit genotype. Now we have

$$w_{\text{max}} = a + bx_{\text{max}}$$

and

$$\overline{w} = a + b\overline{x} = 1$$
 by convention

It then follows directly that

$$L = \frac{cov_{\rm G}(x_{\rm max} - \bar{x})}{V_{\rm Gx} + cov_{\rm G}(x_{\rm max} - \bar{x})}$$

If the change per generation in the mean of the character is known, then

$$L = \frac{\Delta \bar{x}(x_{\text{max}} - \bar{x})}{V_{\text{Gx}} + \Delta \bar{x}(x_{\text{max}} - \bar{x})}$$

The genetic load is an important quantity to know because it measures the intensity of natural selection. If fitness is the probability of survival, then the genetic load is the proportion of the deaths which arise from variations in fitness. Thus it L is large, a population may be in danger

of extinction. For example, suppose a continuous series of fossils shows a change to a new form. During a period of change, we can find $\Delta \bar{x}$ if we know the number of generations that has passed. x_{max} will be the value of the character when the new form has finally become stable. \tilde{x} will be the mean at some point in time in the evolutionary process. Thus we can find L at that time. Usually, evolutionary changes occur as populations adapt to new environments. In a new environment x_{max} will have a new value. The shift of \bar{x} away from x_{max} produces the genetic load which may be high if VGx is small. The formula for L shows why a large genetic variance helps a population to adapt to an environmental change: if V_{Gx} is low the genetic load may be high and the population may become extinct before it can adapt itself. It would therefore be interesting to compare the genetic loads in fossil populations which died out and in those that increased in numbers.

Rare Pseudoallelic Crossover between Two Phenotypically Identical Alleles at a Restricted Sublocus of Dumpy in Drosophila melanogaster

The dumpy locus has been extensively mapped $^{1-4}$. Many of the sites within the dumpy gene have phenotypic specificity; that is, mutants of similar phenotypes map at the same restricted part of the region. A series of mutants which show an ov phenotype (oblique wings and thoracic vortices) were mapped to the right of lv^1 and to the left of v^2 (ref. 4). The ov mutants are viable as homozygotes and in combination with each other, except for ov^h , which is a facultative lethal in the homozygote but which is viable with the other ov alleles. The ov^h allele also shows a more extreme phenotype, and it is distinguishable in combination with other ov mutants by a more extreme phenotype. A crossover between ov^1 and ov^h was obtained by Southin. The work reported here was carried out using other ov alleles of indistinguishable phenotype (ov^1 and ov^{52}) in an attempt to establish critically the fine structure of the dumpy locus by obtaining crossovers between these alleles.

For the cross reported here, the virgin females used were 3-6 days old and the males were 1-7 days old. The flies were mated in groups of twenty males and twenty females and transferred to fresh medium every 3 days to establish four groups of bottles. The progeny were scored every other day, starting with the tenth day and continuing until the sixteenth day. The flies were cultured

at 27° C.

Virgin females of the genotype $ed\ ov^1\ cl/ov^{52b}$ were mated to males $ov^h/lv\ Cy$. The exceptional crossover type obtained was a female phenotypically wild type. On mating to an $ed\ ov^1\ cl$ male, the resulting progeny, excluding non-virginity, were $\sin x + cl/ed\ ov\ cl$, and five $ov^h/ed\ ov^1\ cl$. The progeny test indicates that the genotype of the exceptional female was $+ + cl/ov^h$. It is therefore unlikely that this exceptional female arose by mutation in either of the parental chromosomes, for this occurrence would require at least two simultaneous mutational events (the probability of such an occurrence would be

approximately 1 in 10°). It is also unlikely that the exception is caused by some conversion event, for the chromosome is recombinant for outside markers. It is reasonable to assume that this exception arose from a recombination event between the alleles ov^1 and ov^{52b} in a parental female. The resulting recombinant chromosome (++cl) establishes the position of ov^{52b} with respect to ov^1 ; ov^{52b} is to the right of ov^1 . A map of the "ov sublocus" may be drawn as follows, with three separate sites, because ov^h is known to be to the left of ov^1 .

 ov^h ov^1 ov^{52b}

The discovery of a crossover between phenotypically identical alleles critically establishes the fine structure of the dumpy locus; otherwise, it would be necessary to propose that the alleles of the dumpy region (even phenotypically identical alleles which map in contiguous parts of the map) each constitute a separate gene. This ad hoc hypothesis is rendered unlikely by the rare frequency of this recombinant event. The upper fiducial limit for this frequency (P=0.05) is $5.57/222,688=2.5 \times$ 10-3 map units⁶. The distance between these alleles is likely to be less than 0.0025 map units. If the dumpy gene has a map distance of 0.1 map units between the most distant markers in the gene, the entire map could accommodate at least forty sites. A more probable estimate would be several hundred sites; the lower fiducial limit (P = 0.05) would give as many as 10^4 sites². It is more reasonable to assume that these sites represent many mutable sites within one or a few genes rather than a large number of separate genes. Within the limits of such estimates, at least, these results argue for fine structure within the dumpy locus.

CYTOLOGY

Transformation of Epithelial Cells in vitro

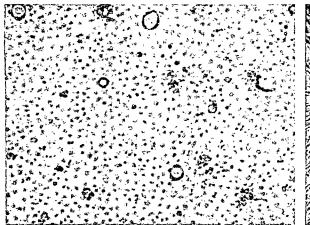

DURING attempts to demonstrate replication of herpes simplex virus in cultures of human leucocytes1, we observed that supernatants from uninoculated leucocyte cultures induced a morphological transformation when added to primary cultures of human amnion cells. When the leucocyte culture fluid was added, the human amnion cells became transformed from epithelial to fibroblast-like cells. This leucocyte factor was produced in cultures of human blood cells which contained the mitogenic agent phytohaemagglutinin (PHA; phytohaemagglutinin-M, Difco), and was found only in the extracellular medium. Neither extracts of leucocytes nor supernatants of leucocyte cultures prepared without PHA possessed this activity. We have called this factor which induces metamorphosis, "MF". Preliminary observations indicate that it is produced by lymphocytes.

Cultures of primary human amnion cells were prepared from human placentas according to generally accepted techniques². Maintenance medium consisted of 45 per cent Hanks salts, 45 per cent bovine amniotic fluid, 5 per cent beef embryo extract, 5 per cent inactivated horse serum and 100 units of penicillin and 100 µg of streptomycin/ml. Cells were maintained in stationary culture in 16 x 150 mm stoppered tubes and were regularly re-fed until a confluent sheet of epithelial cells was obtained. Only confluent cell sheets were used for assay. presence of transformation was determined by direct microscopic examination under low magnification. In several experiments, additional human epithelial cell cultures (HeLa, gingival and human kidney) were also tested for their response to this factor. These cultures were established and maintained by standard techniques2. Human leucocytes were obtained according to methods previously described3. The leucocyte cultures were established with 1×10^{6} lymphocytes/ml. and usually contained 60-80 per cent lymphocytes, 20-40 per cent neutrophils and 1-2 per cent monocytes. These cells were maintained in medium 199 (Earle's salts) and 25 per cent inactivated calf serum. Cells were stimulated with PHA, using a dose which had been previously determined to give maximum DNA synthesis in such cultures. Control leucocyte cultures without PHA were similarly prepared and maintained. Leucocyte cultures were usually killed after 4 days; the cells were spun at 300g for 5 min and the supernatant was separated. Serial dilutions, or undiluted samples of this supernatant of 0.2 ml. volume. were added to the 1 ml. of medium overlying the epithelial cell cultures, and daily observations were made. morphological appearance of the amnion cells before and after exposure to the leucocyte supernatant is shown in Fig. 1. The untreated cell sheet (left) consisted of large, round epithelial cells with dense nuclei and indistinct cytoplasmic boundaries. After addition of metamorphosing factor, the amnion cells sequentially became squared, then triangular, and finally spindle-shaped and tightly whorled. The fully transformed cells were characterized by distinct cytoplasm and cell boundaries. This sequence of transformation took about 5 days. Similar transformation was also observed in cultures of HeLa, gingival and human renal cells. Control preparations consisting of medium 199 with an appropriate amount of PHA did not induce morphological alterations when added to the epithelial cell cultures. In addition, transformation to fibroblast-like cells was not observed with the supernatant from lymphocyte cultures prepared without PHA, nor with extracts of such cultures. The quantity of metamorphosing factor was somewhat variable in different leucocyte cultures, ranging from 1:2 to 1:64. In experiments with varying percentages of lymphocytes and neutrophils, the titre of this material was proportional to the number of lymphocytes.

We have made some preliminary attempts to characterize the factor which was produced in the leucocyte cultures. The factor was retained in a dialysis bag, and there was no loss of activity with dialysis against fresh medium 199. The metamorphosing effect was therefore not the result of addition or removal of small sized metabolites by the leucocytes. The transforming activity was destroyed by boiling the leucocyte supernatant for 10 min.

Our data provide evidence that lymphocytes may influence other cells. The significance of our observations in vivo remains to be determined. It is possible, however, that the elaboration of this substance by lymphocytes which are present in areas of inflammation and wound repair could be responsible for initiating connective tissue proliferation in these conditions. A mechanism such as this was suggested by Virchow in 1871 (ref. 4).

Gresser⁵ observed that supernatants containing interferon, from human cell cultures infected with virus, produced morphological changes similar to those described in this communication. Although he suggested that the

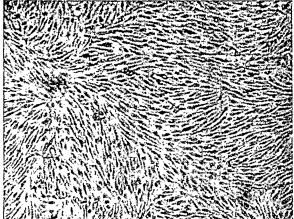

Fig. 1. Primary human amnion cell cultures before and after transformation; left, normal (epithelial morphology); right, transformed (fibroblast-like morphology).

material inducing these changes was interferon, his data indicated that the metamorphogenic and viral-inhibitory activities of his preparations might be dissociable.

Calcium and the Control of Mitosis in the Mammal

INCREASING the calcium concentration in the environment of various types of isolated mammalian and insect cells hastens their progress through mitosis and also counteracts the transient mitotic inhibition following irradiation1-6. The same effects can be produced in the bone marrow and thymus of the whole animal by raising the blood calcium either directly, by injecting calcium salts, or indirectly through the action of parathyroid hormone7,8. Conversely, lowering the calcium level in the medium of isolated normal or irradiated cells reduces their rate of flow into mitosis. Reducing the total calcium level in the blood by injecting the chelating compound ethylene diamine tetra-acetic acid (EDTA) or inorganic phosphate should therefore reduce the mitotic activity in normal and irradiated marrow and thymus in vivo. Contrary to expectations, the present study shows that these compounds in fact stimulated mitosis.

At the start of any experiment, or immediately after irradiation (cobalt-60 γ-radiation), male Sprague-Dawley rats weighing 125 g were injected intraperitoneally with 0·1 mg of colchicine/100 g body weight, and were given a second injection of this same amount 2·5 h later. The progress of cells through mitosis is thus arrested at metaphase and their rate of entry into mitosis can be de-

termined. Either EDTA or disodium hydrogen phosphate was injected intraperitoneally immediately after the first colchicine injection. EDTA (30 mg/ml.) adjusted to pH 7·2 with sodium hydroxide, and disodium hydrogen phosphate solution (80 mmolar) buffered to pH 7·2 in 5 mmolar tris (hydroxymethyl) aminomethane (tris), were given as a dose of 1·0 ml./100 g. Neither the stress of injection nor the tris buffer affected mitotic activity.

At various times after the beginning of the experiment, marrow and thymus cell suspensions were prepared as described elsewhere. Samples of these suspensions were fixed in neutral formalin, stained in Delafield's haematoxylin and the percentage of cells in metaphase was then determined by examining at least a thousand cells.

Blood calcium levels were determined by removing blood samples from the abdominal aorta every 10 min after the injection of EDTA or phosphate; the concentration of total calcium was determined using the colorimetric method of Copp et al.¹⁰, and the ionized calcium concentration was determined with a specific calcium ion electrode (Orion Research, Ltd., Cambridge, Massachusetts).

In the normal animal, bone marrow cells progressed into mitosis in a regular fashion (Fig. 1A), and by 6 h,

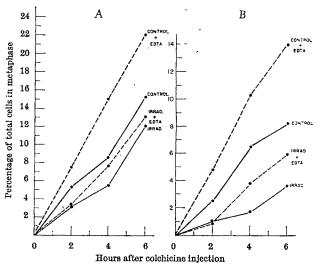

Fig. 1. Effect of EDTA on mitosis in bone marrow and thymus of normal and irradiated Sprague–Dawley rats. A, Bone marrow; B, thymus. In non-irradiated animals, the differences between the percentage of cells trapped at metaphase in normal and EDTA-treated animals were already significant by 2 h after the initial colchicine injection; P < 0.05 (bone marrow) and P < 0.01 (thymus). In Irradiated (100 r.) animals, EDTA caused a significant stimulation of mitosis in the thymus 4 h after the colchicine injection, P < 0.01. The consistent but slight stimulation in the bone marrow was not significant, P < 0.1. Each point is a mean value from at least four rats.

15.3 per cent of the cell population had collected at metaphase. EDTA stimulated mitosis; this stimulation became evident as early as 2 h after treatment, and by 6 h, 22·1 per cent of the cells had reached metaphase (Fig. 1A). Thymus tissue was less active mitotically than marrow and only 8.2 per cent of normal cells reached metaphase in 6 h, but EDTA treatment increased this fraction to 14.0 per cent (Fig. 1B). Phosphate solution also accelerated mitosis in thymus and marrow, but it was slightly less effective than EDTA (Fig. 2).

EDTA and phosphate also stimulated mitosis in the thymus and marrow of irradiated animals. During the first 2 h after irradiation and injection of either compound, there was no demonstrable effect. Between 2 and 6 h, however, a stimulation by these compounds became

evident (Figs. 1 and 2).

Despite the fact that both EDTA and phosphate stimulated mitosis, they also caused a decline in the level of both total and ionized calcium during the first 10 min after injection. The total calcium level subsequently returned to normal, but never exceeded this value. The majority of this restorative calcium surge, however, consisted of ionized calcium and its level rose well above the normal value. Thus 80 min after treatment with EDTA, when the total calcium had returned to normal, as much

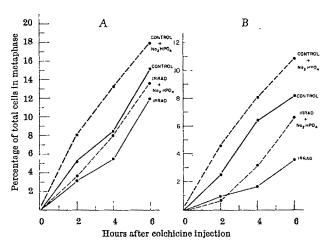

Fig. 2. Effect of disodium hydrogen phosphate on mitosis in bone marrow and thymus of normal and irradiated Sprague-Dawley rats. A, Bone marrow; B, thymus. In non-irradiated animals, the differences between the percentage of cells trapped at metaphase in normal and phosphate-treated animals were already significant by 2 h after the initial colchicine injection in both marrow and thymus (P < 0.01). In tradiated (100 r.) animals phosphate produced a stimulation of mitosis by 4 h in both tissues, P < 0.05 (marrow), P < 0.02 (thymus). Each point is a mean value from at least four rats.

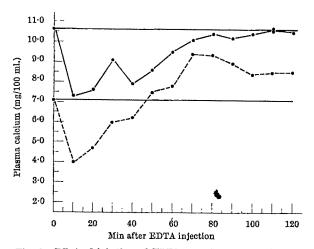

Fig. 3. Effect of injection of EDTA on total (——) and ionized (——) plasma calcium levels. Each point is a mean value from four rats.

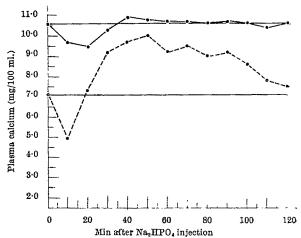

Fig. 4. Effect of 1. Effect of injection of disodium hydrogen phosphate on total and ionized (---) plasma calcium levels. Each point is a mean value from three rats.

as 93 per cent of it was ionized compared with 67 per cent in the normal animal (Figs. 3 and 4).

The unexpected stimulation of mitosis produced by EDTA and phosphate can now be attributed to the abnormally elevated ionized calcium levels which follow the initial lowering of this level induced by these compounds. Mitotic activity can obviously be affected by merely changing the level of ionized, in contrast to bound, calcium in the cellular environment. Plasma calcium levels are controlled by two antagonistic hormones: of these, parathyroid hormone causes a surge of ionized calcium which restores total calcium levels to normal after a sudden depression as in the present study, and calcitonin acts to depress abnormally high levels¹¹⁻¹³. The present results imply therefore that any changes in the balance of these hormones will probably be accompanied by changes in the mitotic activity of the lymphatic and haemopoietic tissues of the animal.

Regardless of the possible mechanisms by which calcium stimulates division in the mitotically competent cell1-3,5,14, in any future consideration of mitotic stimulation and control in the mammal, the role of a calcium and the interplay of the two principal hormones which affect its level cannot be neglected.

We thank P. K. Toelg and T. Youdale for their excellent, technical assistance.

Mitotic Activity in the Chick Embryo Epidermis

AT the age of 9-10 days, the epidermis of the developing chick embryo is composed of two to three undifferentiated cell layers. In the next 10 days of embryonic life, proliferation and differentiation occur in the epidermis which results in the development of a layer of keratinized epidermis, six to ten cells deep. Interrelationship between proliferation and differentiation during the 10 day period has been reported, but the extent of the interreaction is not clear. An interrelationship has been suggested2-4, in which differentiation (keratinization) only begins when cell division has begun to decline. Tonofilaments and tonofibrils, the first indicators of differentiation, are detected2 for the first time in the basal cells of the embryonic epidermis on the thirteenth day. Also on the thirteenth day, labelling experiments with thymidine indicate a reduction in the total number of labelled nuclei3 and these are present only in the basal cell layer after that day.

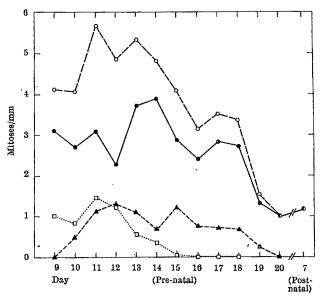

Before the beginning of differentiation on days 10-13, an increase in DNA polymerase activity suggests a possible increase in mitotic activity during that period. The decline in mitotic activity seems to relate to embryonic age. An inhibitor system, which is synthesized as a function of embryonic age, such as that of Bulloughe, could be responsible for the decline in mitotic activity.

To clarify further the state of mitotic activity before and after differentiation, the mitotic activity of the chick embryonic epidermis was examined on days 9 to 20, and was found to be maximum in all cell layers of the 11-13 day old epidermis. The maximal mitotic activity then decreased to the level which was found in the normally keratinizing post-natal epidermis. All stages of mitosis were counted in the epidermis of the chick embryos from day 9 to day 20. The length of the third toe was measured in order to relate the development of the embryo to the chronological age7. Skin specimens were obtained from The tissue was imthe metatarsal region of the leg. mediately fixed in 3 per cent acetic acid-Zenker's fluid for 30 min or in Cajals special for 12-18 h.

Serial paraffin sections, 7µ thick, were cut and the sections were overstained with Harris's haematoxylin. The sections were then decolourized in acid alcohol and were counterstained with eosin or FCF fast green. The number of mitoses in all cell layers were counted along the lengths of basement membrane, using an ocular micrometer. Mitotic counts were carried out on two complete sets of samples obtained from two chick embryos on days 9 to 20. An average length of 40 mm and 22 mm, respectively, was counted for samples of each set. By counting the number of nuclei per unit length, it was found that the width of basal cells increased from 5·6μ to 6·5μ between the ninth and seventeenth days.

In this communication, the basal cell layer is defined as the layer immediately adjacent to the basement membrane. The peridermal cell layer is the outermost layer composed of flattened cells, each containing a small The intermediate cell layers consist of cells nucleus. between the basal cell layer and the peridermal layer. In Fig. 1 the number of mitoses/mm of basement membrane for the different cell layers of the epidermis is plotted as a function of the foetal age of the chick skin. These plots indicate that in the early epidermis (age 9 days) mitotic activity is present chiefly in the basal cell layer. Mitotic activity in the intermediate and peridermal layers increases after the ninth day of embryonic life. The maximum mitotic activity of these cell layers is found on the eleventh day for peridermal, the twelfth to thirteenth day for intermediate cells, and the thirteenth to fourteenth day for the basal cell layer.

In the periderm, the maximum mitotic activity of the eleventh day decreases and at days 15-16 cell division ceases simultaneously with the shedding of the peri-

dermal layer. The decrease from peak mitotic activity of the basal and intermediate layers seems to be tentatively halted at days 17-18. The mitotic activity then continues to decrease to the post-natal level.

The differences in mitoses/mm between days 9-20 are much greater than can be explained by the small differences (10-20 per cent)⁸ in cell density occurring during this period. The results indicate that, before differentiation starts, there is an increase in mitotic activity in which all cell layers of the epidermis become germinative. The stimulation of mitotic activity decreases until days 17-18 when there is a weaker stimulation. This event coincides with the appearance of the stratum corneum, the end product of keratinization. As foetal life ends for the chick, the epidermis assumes its post-natal role which is the continuous production of stratum corneum, with the germinative layer supplying an adequate number of cells for maintenance of the epidermis.

The increase in mitotic events (days 11-13) is in agreement with the increase in DNA polymerase activity found on days 10-13 (ref. 5). The decline in mitotic activity could be the result of a factor or factors which reverse the apparent induction of DNA polymerase activity or the appearance of a mitotic inhibitor system. A mitotic inhibitor system, similar to that of Bullough's chalone-adrenaline epidermal mitotic inhibitor system, could be activated by increased cellular synthesis of the chalone and adrenaline after day 13.

The interrelationship, if any, between possible stimulants and inhibitors of mitosis during epidermal development and differentiation is being further investigated.

In writing any scientific work the principal difficulty resides not so much in what to put in as in what to leave out, and the problem becomes the more acute the further one moves from the strictly professional towards the more popular. At the latter level it is not only a matter of what topics and concepts to discuss but also of how much general introductory explanation must be provided so that the intended reader is able to follow the arguments that are subsequently to be advanced. In so far as phenomena are merely being described all is well or nearly so, but if theoretical explanations of these phenomena are to be advanced, and also explanations of the patterns into which they fit, more and more props and aids must be provided if the reader is not to fall by the wayside.

The group of books under consideration, the first batch of a series of Contemporary Science Paperbacks, can be broadly described as being directed at the educated scientific layman, though some at least of them are perhaps a little more nearly professional than is commonly the case with such an aim. Thus The Shapes of Molecules, which deals with carbohydrate polymers, really requires some previous knowledge of chemistry, and thorough understanding of Molecular Biophysics would certainly be helped by it. By contrast, Chemical Exchanges in Man and Reproduction and Man, which are somewhat more descriptive, could be read and understood with little in the way of previous knowledge, provided always that the necessary degree of concentration was afforded by the

reader. One of the major dangers with short books such as these is that the author is tempted—and has not always here resisted the temptation—to get rather too much in his introduction dealing with the basic principles, situations and terminology of the subject.

On the physical sciences side, Basic Astronomy does not present any major problems, but The Basis of Modern Physics and still more The Ideas of Physics demand a good deal from the general reader because here it is concepts and more abstract considerations that have to be grappled with: a good deal more difficult to explain satisfactorily and requiring correspondingly greater effort on the part of the reader. By contrast, the demandmade by The Evolution of the Galaxies are less onerous: not that the concepts are significantly simpler, but the focus is somewhat more restricted and they therefore become at least relatively familiar the more rapidly. Life. Mind and Galaxies is interesting because it spans the whole range of physics, chemistry and biology: it is also rather more speculative than most of the other titles in the batch and, though this is not unreasonable in such a field, one rather gets the impression of a search for the spectacular, and the writing is less reasoned and convincing than in most of the other titles.

Attraction and Repulsion is scarcely surprisingly about magnets and this is one of the real successes of the batch. It is about something that is in essence familiar but the explanation and operation of which remain, for most people, mysterious. The author has provided a neat clear and stimulating account that should be of great use and interest to sixth form pupils as well as to a much wider public. The largest book in the group tells of a subject which is impinging increasingly on the lives of us all, Electronic Computers. This is described as being for the general reader, but I suspect that such a person is going to have some trouble in following the argument to the end, for there is quite a bit of electrical engineering theory in it and concepts and situations that are unfamiliar—this is scarcely the book for the entirely uninformed to start on.

Rather sensibly the author of the text on automation has split his work into two volumes, Automation: its Anatomy and Physiology and Automation: its Uses and Consequences. Such a division would scarcely work for all fields, but here it seems to have done very well, for the subject matter falls quite rationally into these divisions, and in the face of many people's fears of what automation may possibly do to their lives detailed and balanced consideration of its use and consequences is The first volume presents an arguvery welcome. ment that is not of itself simple but the treatment is lucid and forthright so that it should be followed fairly readily. The second volume deals essentially with the economic and social possibilities and problems that stem from automation and is the one more likely to be widely read: it should go some way to set at rest the more extreme fears about the widespread introduction of automation.

The last of the fourteen volumes could scarcely be more topical: noise is something that society is increasingly unable to escape from, and the introduction of civilian supersonic aircraft leaves one full of foreboding for the future. The author of Noise and Society makes plain the technical difficulties that are involved in measuring noise, and then, having done so, relates such scientific measurements to the question of general nuisance and, in the extreme, to actual damage to hearing. He leaves us with an impression of his own astonishment at how little has really been done legislatively to afford society any effective protection.

The general claim of the editors of the series is that their volumes "are lucid, compact and authoritative. Through them, scientific and technological ideas and achievements are made readily comprehensible". For the most part, I feel that their claim is justified; compact these volumes certainly are, sometimes just a little too compact for comfort where an author has been anxious to get that little extra bit in that might better have been left out. Lucid the majority of them are, and authoritative too with perhaps an odd exception. Probably more than half of them make scientific and technological ideas and achievements readily comprehensive, the rest make them comprehensible but not perhaps quite so readily as their authors imagined.

Production standards are generally good, line drawings being simple but effective and the black-and-white plates quite well done; the organic chemical formulae that appear in some volumes could be improved, however. All told, an excellent beginning that is to be highly commended, with volumes that are good value for money.

PETER SYKES

DETECTING ESP

Science, Philosophy and ESP By Charles McCreery. Pp. 199. (London: Faber and Faber, 1967.) 32s. 6d. net.

WE might expect ESP to be a proper study for experimental psychologists in the field of perception. But the failure of psychologists, in general, to take such phenomena seriously has led to the establishment of parapsychology, with its own journals and its own research institutions outside the universities. Mr McCreery is a research officer of the Psychophysical Research Unit in Oxford, and his book describes one aspect of the unit's work.

In the foreword by Professor H. H. Price, we are told that Part 1 could very well serve as an introduction to psychical research for readers who have little or no previous knowledge of the subject. Here examples are given of phenomena that have been considered by many people, including eminent scientists and philosophers, to defy explanation in terms of existing scientific knowledge. Its value must, however, be doubted. For, although the main evidence for ESP has been extensively criticized, Mr McCreery's method of dealing with criticism is to ignore it. Thus the remarkable feats of an Italian medium, Eusapia Palladino, are described in some detail. medium, while seated in semi-darkness at a table with her arms and legs held in the grip of members of various investigating committees, was able, according to the account, to cause remarkable manifestations of psychical The table rose from the floor; musical phenomena. instruments positioned on a table behind her emitted sounds; ghostly fingers pinched the learned investigators. But no mention is made of the fact that when she visited the United States her modus operandi was completely revealed. The reader who wishes to know more about this lady should consult a report made by Hugo Munsterburg concerning a sitting carried out in the psychology department at Harvard1; and a report, published in Science, submitted by a group of scientists at Columbia Uni-The latter report describes how investigators versity². concealed under the table saw it levitate on several They also observed Eusapia's footwork at occasions. close range, and the manner in which she assisted its movement. Experts in subterfuge sitting at the table were able to turn on or off other psychical phenomena by decreasing or increasing the effectiveness with which they controlled the movements of the medium's arms.

Again, Mr McCreery describes the well-known experiment in which it was claimed that Basil Shackleton could predict the identities of cards seen by a second person about two seconds after he had recorded his prediction, but no mention is made of criticisms of the experiment, nor of information that has come to light which reflects on its value.

Mr McCreery makes it clear that he is well aware of the necessity for checking the result of an experiment by repeating it and confirming the observations. The reader is, however, not only interested in cases where a series of observations have been confirmed by other investigators, but also with instances, like the investigation of Eusapia Palladino, where further investigations have not only failed to confirm the original reports but have also given clear indications that the original investigators were led

In general, this first part of the book must be regarded as an attempt to persuade the reader that the phenomena are genuine. It would have presented a far more impressive picture if Mr McCreery had acquainted his readers with the various criticisms together with his reasons for

disregarding them.

In the second part of his book Mr McCreery is concerned with methods by means of which the evidence for ESP and other psychical phenomena may be made more. convincing. His problem arises because ESP, if it exists, has quite unpredictable properties. For example, Basil Shackleton, according to Mr McCreery, only obtained high scores when a particular investigator was present, and, because he lost his ability to score at all shortly after the termination of the experiments, it was not possible to provide independent confirmation of his ESP ability. Other high-scoring subjects have also lost their ESP abilities shortly after the conclusion of an experiment. The problem is made even more difficult by the fact that individuals who can consistently obtain high scores seem to have disappeared altogether during the past few years. Some investigators claim that they can isolate individuals who have only slight ESP ability. It might therefore be expected, if a sufficiently large group of such people all guess the same cards, that a suitable statistical analysis would enable the cards to be identified with a high degree of success. But for some reason ESP does not operate in this fashion.

Mr McCreery suggests that it may be possible to improve the scoring rate by employing techniques which will enable the investigator to test subjects at times when their ESP abilities are at their peak. He writes, "To introduce an analogy: suppose that a cricketer found that he only scored more than fifty runs on days when his visual acuity was at its maximum. Then to improve his batting average he would only have to abstain from play on days when this condition did not obtain—if this were possible.

"To complete the analogy with the card-guesser, let us suppose that the batsman is not able to tell introspectively whether his acuity is at its maximum or not. Then it might be possible for him to employ a coach to apply an objective test, such as the letter-test used by opticians, whenever he wished to decide whether to volunteer for his team or not.'

If the subject in an ESP experiment knew when he got a hit and when he got a miss, it would be possible to select occasions when he thought he had got a hit and thus improve his score. ESP subjects, it seems, however, have no idea when they are successful or not.

Mr McCreery's solution is to use physiological concomitants of mental states which can be detected by means of suitable apparatus. These, he thinks, will enable him to monitor the subject for states conducive to ESP. After discussing a number of possibilities, he makes the follow-

ing predictions:
"The EEG record of the conscious ESP subject at the time of the occurrence of ESP will show the following

characteristics.

(1) Continuous alpha activity, which is

- (2) Slightly accelerated (or at the upper limit of its range of frequency for that particular subject).
- (3) No delta activity, and(4) No theta activity."

He continues:

"More tentatively, it is suggested that during the occurrence of ESP the conscious ESP subject may show:

(5) Decreased muscle-tone and

(6) Increased alveolar carbon dioxide pressure."

Whether we have much faith in his predictions or not, it must be agreed that Mr McCreery has faced up to a major problem facing parapsychologists. It remains for him to test his predictions and report the result. He must, however, pay more attention to those pitfalls encountered by previous ESP investigators than he has done in the first part of his book. C. E. M. HANSEL

MODEST PHYSICIST'S THOUGHTS

Symmetries and Relections

Scientific Essays. By Eugene P. Wigner. Pp. viii + 280. (Bloomington and London: Indiana University Press, \$7.50; 568.

This volume is a collection of addresses and essays by Professor Eugene P. Wigner, Nobel Laureate in physics. A wide range of topics is covered, including discussions on the meaning and interpretation of the basic concepts of physics, reminiscences of the first man-made nuclear chain reaction in Chicago in 1942, biographies of Enrico Fermi and John von Neumann, and evaluation of the problems facing humanity in a nuclear age. In all a fascinating collection, which will appeal to a much wider audience than merely physicists. On the whole the level is non-specialist, and these essays and talks are concerned more with aims, motives and meaning of science than with details of the author's own field, theoretical physics. Indeed, copies of this book could well be included in the libraries of high schools.

The reader may be interested in a quotation from Wigner's J. F. Carlson lecture, which forms the final "The Growth of Science-Its Promise and Its Dangers": "Already, we have more trouble in controlling the spread of dangerous and of habit-forming drugs than of nuclear weapons, and they have caused more unhappiness than the latter." GRAHAM DERRICK

PROSPECT OF EARTH

Viewing Weather from Space By E. C. Barrett. (Longmans' Geography Paperbacks.) Pp. xii+140+8 plates. (London: Longmans, Green and Co., Ltd., 1967.) 21s. net.

It is always useful to see another point of view and in certain fields of scientific endeavour it is extremely helpful to see from another viewing point. This is most true in the study of the Earth's atmosphere, the "ocean of air" drifting around and above us largely unseen if not entirely unperceived. How technology has aided the meteorologist, aeronomer and ionospheric physicist by providing the "topside soundings" is a fascinating story, largely told in press releases and popular articles, but a tale that loses nothing in retelling especially in such a concise and informative way as in Mr. Barrett's slim volume. Viewing Weather from Space is broad in its concept; its writer aims at a fairly general audience and seeks to show how the development of the meteorological satellite has stimulated new methods and revised concepts in the atmospheric sciences. Everyman is hard to please and it is possible that this book will find most favour with students, to whom its size, price and review nature will appeal.

It must be admitted that virtually all of the research in meteorological satellite development, data evaluation and utilization has been performed in the United States while the rest of the world has benefited in terms of improved forecasts. The book perforce is a summary of US experience, but this implies no geographical limitation in scope because most features revealed in satellite pictures

are the result of fundamental processes in the free atmo-This raises the question as to whether those chapters of the book which follow conventional climatological divisions of the atmosphere (the fourth, fifth and sixth chapters, "The General Circulation . . .", "The Tropical Atmosphere" and "Weather Systems in Temperate Latitudes") represent logical subdivisions or whether it might not have been better to present a framework based on the basic geometric structures which have been revealed by the pictures themselves, for example, vortices, linear features, cellular patterns and so on. Admittedly, it would be more difficult to insert the more basic clements of meteorological theory into this type of framework, but the approach could be considered more appropriate to a book dealing with satellite pictures and their features.

It is the photographs which are the basis for the work, so could not the publisher have avoided binding the plates in the centre of the book? No doubt this represents a saving in production costs, but it is a source of irritation to be faced with the choice of committing them to memory or turning back time after time to find the specific example. Economics probably prevented the author from including more examples, but could he not have substituted some sketch reproductions to illustrate his discussion? The quality of the illustrations is very high, but some of the diagrams are rather aged; thus the hurricane cross-section shows no primary and secondary cells or "hot tower" and the general circulation still has a driven meridional cell in middle latitudes. Forecasting in middle latitudes has been rendered a disservice when Mr Barrett states that in the middle troposphere isobars and isotherms tend to parallel each other, but then medium range forecasts are not mentioned as part of the forecaster's lot. What is important is that the operational value of photographs or nephanalyses is stressed. This brings us to the final point; at the moment the television camera satellite is an exciting new tool, but very soon it will be just another instrumental aid. Whether it will lead research workers to new conclusions about the atmosphere and its mechanisms is very much a matter for debate, but it certainly will excel at its designated task of surveillance and thue improve our synoptic appreciation. Viewing Weather from Space looks to the instrumental advances of the future and performs a service in putting into easily digested perspective the present role of the weather eye in the sky. P. Larsson

SULPHUR HETEROCYCLICS

Multi-Sulfur and Sulfur and Oxygen Five- and Sixmembered Heterocycles

By David S. Breslow and Herman Skolnik. Part 1: Pp. xxii+1-610. Part 2: Pp. xviii+611-1403. (The Chemistry of Heterocyclic Compounds: a Series of Mono. graphs, Vol. 21, Parts 1 and 2.) (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1966.) 600s.

THE literature of organic sulphur compounds has recently made some notable gains, and the addition of this volume to the well-known Interscience series on heterocyclic compounds provides useful coverage for a hitherto poorly documented area. More than two hundred parent ring systems are encompassed by the title, although many of these have only a small literature, having been only rarely studied for their intrinsic interest.

The two parts of the volume deal respectively with fiveand six-membered rings, and, as might be expected, the major sections in each concern systems containing two hetero-atoms. These include the more familiar 1,2- and 1,3-dithia- and oxathia-heterocycles, and the 1,4-dithianes; sizable chapters are also merited by cyclic sulphite, sulphate and sulphonate esters. A final chapter, curiously unadvertised in the title, is devoted to analogous systems containing selenium and tellurium; its comparative brevity reflects the meagre literature associated with these compounds.

Classification by ring size inevitably results in some duplication in the type of chemistry covered in the two parts. This is, however, a comprehensive reference work with the emphasis on preparative and descriptive detail rather than on mechanistic generalities. Thorough and painstaking reviews of the literature relating to each major parent compound are given, together with critical evaluation and reinterpretation where needed. As in other recent volumes in this series, comprehensive tables of individual compounds, with their associated physical data and literature references, accompany each section.

The authors have paid particular attention to nomenclature, often very confused in this field, and to the compilation of a systematic index. They have adopted the useful device of adding to each page citation pertaining to a listed compound a suffix indicating the type of information available on that page. While this undoubtedly aids the location of specific data concerning individual compounds, the index itself seems oriented almost entirely to this end, and contains few general entries relating to reaction type.

Nevertheless, the volume is an impressive contribution to the reference literature of organo-sulphur chemistry. It should be of value not only to the specialist in sulphur heterocyclics, but also to those interested in the uses and potentialities of many of the systems described, in general organic synthesis. J. D. Hobson

NEW JOURNAL

Journal of Molecular Structure

Vol. 1, No. 1 (October 1967). Published bimonthly. Pp. 1-116. Subscription price: 180s.; \$25; D.fl. 90 per volume (6 issues), plus postage. (Amsterdam: Elsevier Publishing Company, 1967.)

THE increasing application of a wide variety of physical techniques is leading to more and more structural information about molecules. The appearance of a new journal devoted entirely to molecular structure evidences the view that the field deserves a focal point of publication. The editors, Professors Orville-Thomas, Lecomte and Lippert, will cover English, French and German speaking territories. There is an equally distinguished editorial board whose members span North and South America and Europe. A team of this distinction augurs well for the success of the new journal.

One of the criteria of success must be whether the journal can become a real centre of publication of structural studies. It is clearly far too early to attempt to judge this at the present stage. The editors appear to be taking a very wide interpretation of the term "molecular structure". In the first issue of the journal one paper presents new structural information in the sense of internuclear distances and angles; it is a very interesting paper, combining, as it does, both microwave and electron diffraction data in a structural determination. Other papers provide evidence and arguments for certain atomic configurations or molecular conformations. Others provide infrared assignments in terms of assumed structures. Another is concerned with time-dependent interactions and yet another with molecular interactions in solution. Only with further issues will the range of the structural umbrella become clear.

There may well be some who, recognizing the need for journals to meet changing needs, nevertheless fear the contribution that such developments may make to further fragmentation in science. They may feel that these needs might be best met and the dangers averted by the appearance of some such journal as a "European Journal of Chemical Physics". However this may be, it is likely that many will watch with interest the development of this new journal. D. J. MILLEN

ENZYMES AND MITOCHONDRIA

Methods in Enzymology

Vol. 10: Oxidation and Phosphorylation. Edited by Ronald W. Estabrook and Maynard E. Pullman. Pp. xx+818. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 236s.

THE aim of this volume is, in the words of its editors. "to provide not only the specialist and the advanced student but also investigators from other areas of research with a single authoritative source for the vast and often difficult to retrieve and evaluate methodology associated with mitochondrial research". Contributions by nearly 150 experts in this field assure that the volume is both authoritative and topical. A particularly pleasing aspect of the contents is the inclusion of sections that are neither strictly mitochondrial nor enzymological, but are nevertheless highly relevant to mitochondrial research. For instance, the articles on microbial phosphorylating systems, electron paramagnetic resonance, the preparation of antisera to respiratory chain components, the preparation of respiratory chain mutants of yeast, and the biological applications of ion-specific glass electrodes should stimulate wider use of these potentially penetrating

Editorial interference is clearly minimal, and however convenient this may have been for the contributors it may lead to some confusion on the part of the reader, and particularly those from other areas of research. For instance, the five different preparations described for various types of NADH dehydrogenase from cardiac muscle could benefit from an independent critique. The reader is also likely to be confused by the section devoted to the preparation of inner and outer mitochondrial membranes, where the fractionation scheme of one article gives results that are diametrically opposed to those of another. Although it is impossible for a book such as this to be both up to date and also non-controversial, an appropriate but unbiased editorial note would assist the uninitiated reader in distinguishing between accepted and disputed methods.

A number of methods described in previous volumes of this series are not redescribed, presumably because the original accounts are still adequate. In at least one case of wide usage, that of optical techniques, the present ready availability and relatively low price of the com-ponents required for the assembly of fluorimeters and double-beam spectrophotometers suggests that an extensive article of "do-it-yourself" methods would be widely acceptable.

The volume goes far towards making a central point of reference in the methodology of mitochondrial research; a certain failure in the editors' achievement of their aim is both to be expected and desired from a subject that is still a field of active and novel experimentation. The success of this volume will be judged by the speed with which it renders itself obsolete or inadequate.
P. B. GARLAND

APPLIED ENZYME KINETICS

Design of Active-Site-Directed Irreversible Enzyme Inhibitors

The Organic Chemistry of the Enzymic Active-Site. By B. R. Baker. Pp. xiii + 325. (New York and London: John Wiley and Sons, Inc., 1967.) 108s.

STUDIES of enzyme inhibition have important implications in many areas of biochemistry and medicine, and are fundamental in chemotherapy and toxicology, as well as in investigations of enzyme structure, function and mechanism. Both the practical and academic aspects of the subject are well illustrated in this book, which should appeal equally to the enzymologist and the pharmacologist. From the results of kinetic measurements with large numbers of substrates and inhibitors of systematically varied structure, detailed conclusions are drawn about the modes of binding to several enzymes. The value of this type of comparative kinetic investigation of enzymes with wide specificity was shown by the work of Neurath, Niemann and others on chymotrypsin. work, and the results of similar studies of a number of enzymes concerned in nucleotide metabolism, largely from Professor Baker's own laboratory, are considered here as the first stage in a systematic approach to the design of "active-site-directed irreversible inhibitors" for these enzymes.

This term was coined by Professor Baker to describe a compound with the properties of both a reversible competitive inhibitor and an irreversible inhibitor. This can form a covalent bond with the enzyme by facile neighbouring-group reaction within the reversible complex, thereby making the inhibition irreversible and "labelling" a single group near the active centre. Such a bifunctional inhibitor is likely to be more specific and potent than either of its component types. Di-isopropyl phosphofluoridate was the first to be discovered, and its mechanism and that of azaserine, are considered in the introductory chapter, together with the general principles and potentialities of this kind of inhibition, and some general problems of chemotherapy illustrated by 6-mercaptopurine. In a later chapter, more recent work on other "affinity labelling" reagents for chymotrypsin is discussed, and the rate equations for enzyme inactivation by various mechanisms are derived.

The second chapter is a valuable survey of the types of bonds involved in reversible enzyme-substrate and inhibitor compounds, and the potentialities for such bond formation by protein groups and common functional groups of substrates and inhibitors. Kinetic "binding" studies with chymotrypsin, trypsin, thymidine kinase and phosphorylase, adenylosuccinate synthetase and guanine de-aminase are discussed in detail in succeeding chapters, with the objective of discovering which substrate or inhibitor groups are needed for strong binding, and where a bulky alkylating group, for example, can be tolerated

on a good reversible inhibitor.

The last stage in the design of an inhibitor of value in chemotherapy, which is Professor Baker's principal concern, is based on the idea that greater specificity will be achieved if the alkylating group can bridge to a nucleophilic enzyme group outside an active centre, where analogous enzymes from a different species or tissues may differ in structure. The last half of the book is devoted to systematic studies to this end with lactate and glutamate dehydrogenases, tetrahydrofolate dehydrogenase, adenosine de-aminase and thymidilate synthetase. For the first four of these, active-site-directed irreversible inhibitors were discovered; selective specificity for heart and skeletal muscle lactic dehydrogenase was also achieved, but not as yet the main objective of species specificity for the other enzymes. The book closes with a chapter on enzyme-specific columns.

In the face of such a formidable body of kinetic data and such fascinating and detailed rationalizations in terms of binding, it may seem carping to wish for some justification for the interpretation of Michaelis constants and inhibitor constants as dissociation constants, especially for the two-substrate and coenzyme-substrate enzymes studied. Some of the inconsistencies in the rationalizations may well be due to comparisons of K_m and K_i , and to an over-simplified treatment of inhibition. While it may be better to base the design of inhibitors for chemotherapy on doubtful generalizations than to proceed by random

synthesis, some of the conclusions about mechanisms may be seriously challenged, and the reader interested in this aspect must be aware of the assumptions underlying the whole approach. Nevertheless, this stimulating and timely book can be recommended to all concerned in any way with enzyme action. There are numerous references to the recent literature, the author's style and presentation are clear, and very few misprints have escaped the proof reader. Consequently, for a book in which some hundreds of compounds are listed in tables and discussed by number in the text, it is remarkably easy to read. K. DALZIEL

MARINE MICROBIOLOGY

Microbial Population of Oceans and Seas

By A. E. Kriss, I. E. Mishustina, I. N. Mitskevich and E. V. Zemtsova. Translated by K. Syers. Pp. 287. (London: Edward Arnold (Publishers), Ltd., 1967.) 90s. Microbial Population of Oceans and Seas by Kriss. Mishustina, Mitskevich and Zemtsova is similar in many respects to Professor Kriss's previous book, Marine Microbiology (Deep Sea), to which it is a supplement. The book itself is primarily an account of the authors' own work describing the species of micro-organisms they have isolated from the sea and the physiological and biochemical properties of their isolates.

The book is divided into three sections. section includes useful lists of species of micro-organisms isolated from the sea by various workers, an account of the salt requirement of the authors' isolates, the viability of these organisms, attacks on the work of Sorokin and Kuznetsov, as well as a chapter dealing with the distribution of organic matter in the sea. The latter chapter is in reality an account of distribution of bacterial numbers in the sea, presumed by the authors to be a measure of the amount of labile organic matter. This chapter contains some rather surprising statements about the distribution of organic material in the sea.

The next section is largely devoted to a description of the occurrence and features of some 200 species of bacteria and fungi isolated by the authors from various The bacteria, comprising the majority of the isolates, are classified by a Russian key. This section also contains a chapter devoted to the occurrence of bacteriocidal properties and bacteriophages among their isolates.

The final section contains short chapters on geographical distribution of bacterial numbers, a general discussion of the distribution of bacterial species and a detailed account of the occurrence of one particular species: Bacterium (probably Achromobacter) agile. In addition there is a chapter describing the variation in biochemical activities of species isolated from various localities. The authors place considerable stress on the results of this study, and in view of this it is unfortunate that the value of the tests employed is not discussed: for the ability to oxidize lactose or to produce hydrogen sulphide from proteins would not seem to be an important biochemical function of a marine micro-organism. The results of this chapter in conjunction with those of the distribution of organic matter lead the authors to a rather improbable conclusion regarding the cycle of organic material in the ocean and oceanic circulation in general.

The book suffers from a general shallowness of approach as well as containing some rather questionable assumptions and statements. Professor Fogg's editorial comments are in this respect invaluable, directing attention to contentious points. The text contains an enormous amount of information, much of which is unassimilated; consequently the book will be useful to the specialist primarily: it would leave the beginner floundering some-P. J. LE B. WILLIAMS

Announcements

A GRANT of £90,000 is to be awarded, over a period of five years, to the Institute of Operational Research by the Ministry of Health to enable the Institute to expand the work it does for hospital authorities. The purpose of the new institute is to undertake social research by applying the disciplines of operational research and the social sciences. In addition to tackling problems in planning which arise in the management of industrial organizations and public and social services, the institute also provides advisory and training services related to its field of research. At present the institute is undertaking studies commissioned by the governors of the teaching hospital in Birmingham, by the Birmingham, Wessex, and Manchester Regional Hospital Boards, and by the Ministry itself.

THE Messel Medal of the Society of Chemical Industry will be presented to Sir Paul Chambers during the annual general meeting of the society in July 1968.

Meetings

VALENCE and Reactivity, January 9-11, Oxford (Scientific Affairs Officer, The Chemical Society, Burlington House, Piccadilly, London, W1).

Low and Medium Energy Nuclear Physics, March 27–29, 1968, Atomic Energy Research Establishment, Harwell (The Meetings Officer, The Institute of Physics and The Physical Society, 47 Belgrave Square, London, SW1).

FAR Infrared Properties of Solids, August 5-23, 1968 Delft (Professor S. S. Mitra, University of Rhode Island, Kingston, Rhode Island).

MEDICAL Radioisotope Scintigraphy, August 6-15, 1968, Salzburg (Dr G. J. Hine, Section of Nuclear Medicine, IAEA, Vienna I).

SECOND International Liquid Crystal Conference, August 12–16, 1968, Kent State University (Dr Glenn H. Brown, Director, Liquid Crystal Institute, and Conference Chairman, Kent State University, Kent, Ohio 44240).

HISTOCHEMISTRY and Cytochemistry, August 18-22, 1968, New York City (Dr R. M. Rosenbaum, Secretary, Third International Congress of Histochemistry and Cytochemistry, Department of Pathology, Albert Einstein College of Medicine, New York, New York 10461).

LABORATORY Astrophysics, September 2-6, 1968, Lunteren (J. Rosenberg, Astronomical Observatory "Sonnenborgh", Servaasbolwerk 12, Utrecht, The Netherlands).

Solid State Devices, September 3-6, 1968, University of Manchester Institute of Science and Technology (The Meetings Officer, The Institute of Physics and The Physical Society, 47 Belgrave Square, London, SW1).

MOLECULAR Structure and Spectroscopy, September 3-7, 1968, Ohio State University (Professor K. Narahari Rao, Molecular Spectroscopy Symposium, Department of Physics, The Ohio State University, 174 West 18th Avenue, Columbus, Ohio 43210).

Physics in the Metal Forming Industries, November 19-21, 1968, Harrogate (The Meetings Officer, The Institute of Physics and The Physical Society, 47 Belgrave Square, London, SW1).

Physico-chemical Mechanisms of Carcinogenesis, October 21-25, 1968, Jerusalem (Professor E. D. Bergmann, Department of Chemistry, The Hebrew University, Jerusalem, Israel).

ERRATUM. In line 5 of the short note on "Protein from Petroleum" (*Nature*, 216, 843; 1967) we should, of course, have referred to the BP group, not the Shell BP group.

ERRATUM. On page 1124 of the article "Cerebral Potentials evoked by Pattern Reversal and their Suppression in Visual Rivalry," *Nature*, 216, 1123; 1967, lines 18 and 19 should read "... was 200 ft. lamberts" and not "... was 200 ft. lumens".

ERRATUM. The Symposium on Quantitative Thin Layer and Paper Chromatography on January 3 and 4, which was mentioned in the article "Thin-Layer Chromatography" by E. J. Shellard (Nature, 216, 1168; 1967), is organized by the Pharmaceutical Society and the Society for Analytical Chemistry, not by the Pharmacological Society, as was stated."

Erratum. In the communication "Factors influencing Lysis of Whole Blood Clots," by Fletcher B. Taylor and Hans J. Müller-Eberhard (*Nature*, 216, 1023; 1967) the second sentence of the legend to Fig. 1 should read: "0·25 ml. aliquots of partially purified rabbit antibodies to: (1) albumin; (2) C'4; (3) C'3; (4) γ M; (5) γ G; (6) α_2 -macroglobulin have been added."

CORRIGENDUM. In the article "Fitting Cosmological Models to the Radio Source Counts" by W. Davidson (Nature, 216, 1076; 1967) the second sentence of the legend to Fig. 2 should read: "The ordinate is normalized so that it gives the relative number of sources per unit of $l(l=\log_{10}P)$, that is, the ordinate is $\alpha\rho(l)P^{3/2}$ where $\rho_0(l)$ is number of sources $m^{-3}l^{-1}$, and $\int n_0(P) dl = 1$."

CORRESPONDENCE

Eradication of Culex pipiens fatigans through Cytoplasmic Incompatibility

SIR,-It would clearly be of the greatest importance to demonstrate that the utilization of cytoplasmic incompatibility can lead to the eradication of any species of mosquito from even the smallest island or "ecological island". In his recent communication under the above title, Laven (Nature, 216, 383; 1967) asserts that he has, in fact, eradicated an isolated population of the filariasis vector C.p. fatigans in the rice-field village of Okpo, Burma. His data undeniably indicate the achievement of a steadily increasing incidence of non-viable eggs, culminating in 100 per cent non-viability on May 9 and 10, 1967. Making due allowance for the duration of the larval and pupal stages, and the fact that a small percentage of the eggs examined on May 8 remained viable, he claimed that "no more adults were expected to emerge after about 10 days". His next sentence, however, reads "Unfortunately, the monsoons started on May 11 and the experiment had to stop." No evidence of any further relevant observations being presented, and larval, pupal and adult C.p. fatigans still being present in the study area at the moment when the coming of the rains profoundly altered local larval habitat availability, the old Scottish legal verdict of "Not proven" therefore applies. While it is much to be hoped that follow-up observations will justify Laven's claim, his data as presented are evidence of no more than population suppression to a low level.

Yours sincerely,

MARSHALL LAIRD, Professor and Head of Biology.

Department of Biology, Memorial University of Newfoundland, St. John's, Newfoundland, Canada.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Tuesday, January 2

SOCIETY FOR EXPERIMENTAL BIOLOGY (at Birkbeck College, Malet Street, London, WCI), at 9.15 a.m.—Sessions of papers in the following fields: "Transport in Plants"; "Development of Chloroplasts"; "Photosynthesis"; "Nutrition of Plants" and "Techniques in Electrophoresis".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 2.30 p.m.—Colloquium in "The Economical Collection of Meteorological Data".

SOCIETY OF CHEMICAL INDUSTRY, MICROBIOLOGY GROUP (in the Engineering Lecture Theatre, University College London, Gower Street, London, WC1), at 2.30 p.m.—Meeting on "Maintenance of Pure Culture Conditions in Industrial Fermentations".

Wednesday, January 3

SOCIETY FOR EXPERIMENTAL BIOLOGY (at Birkbeck College, Malet Street, London, WC1), at 9 a.m.—Sessions of papers in the following fields: "Nucleic Acids in Plants"; "Enzymes in Plants"; "Physiology of Insect Nerve and Muscle"; "General Histochemistry" and "Experimental Zoology".

COLOUR GROUP (Great Britain) (in the Department of Colour Chemistry, The University, Leeds), at 2 p.m.—Dr F. Jones: "Colour in Inorganic Compounds"; Dr G. Hallas: "Colour in Organic Compounds".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, WC2), at 2.30 p.m.—Dr S. Bradbury: "The Microscope" (Juvenile Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m .- Scientific Papers.

SOCIETY OF CHEMICAL INDUSTRY, OILS AND FATS GROUP (at 14 Belgrave Square, London, SW1), at 6.15 p.m.—Dr A. Garton, FRS: "Factors Influencing the Composition of Adipose Tissue Triglycerides".

Wednesday, January 3-Thursday, January 4

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, and the SOCIETY FOR ANALYTICAL CHEMISTRY, THIN LAYER CHROMATOGRAPHY GROUP (at Chelsea (College of Science and Technology, Manresa Road, London, SW3), at 2 p.m. on Wholesday and 9.45 a.m. on Thursday—Symposium on "Quantitative Thin Layer and Paper Chromatography".

Thursday, January 4

SOCIETY FOR EXPERIMENTAL BIOLOGY (In the Botany Theatre, University College London, Gower Street, London, WC1), at 9.15 a.m.—Symposium on "The Structure and Function of Mitochondria", and (at Birkbeck College, Malet Street, London, WC1), at 9.16 a.m.—Sessions of papers in the following fields: "Plant Development"; "Insect Hormones"; and "Invertebrate Physiology". Physiology".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Mr J. H. H. Merriman, OBE: "Changing Patterns in Communications" (Tenth Hunter Memorial Lecture).

Thursday, January 4-Friday, January 5

MINERALOGICAL SOCIETY (in the Department of Mineralogy and Petrology, The University, Downing Place, Cambridge)—Meeting on "The Mineralogy and Petrology of Glaucophane Schists and Associated Rocks".

Friday, January 5

BIOCHEMICAL SOCIETY (in the Department of Biochemistry and Chemistry, The Medical College of St. Bartholomew's Hospital, Charterhouse Square, London, EC1), at 9.30 a.m.—Colloquium on "Properties of Enzymes Attached to Solid Matrices", followed by an Ordinary Meeting in the after-

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE (at the Chelsea College of chence and Technology, Manresa Road, London, SW3), at 10.15 a.m.— Science and Tec Winter Meeting.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Dr H. G. Hopkins and Mr W. A. S. Murray: "The Practical Use of Radar and D. F. Techniques in Locating Earth Satellites".

Monday, January 8

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Discussion Meeting on "Domain Originated Functional Integrated Circuits (DOFICS)" opened by Mr C. P. Sandbank.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Discussion Meeting on "Logarithmically Periodic Aerials" opened by Mr M. F. Radford.

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (joint meeting with the Colloid and Surface Chemistry Group, at 14 Belgrave Square, London, SW1), at 5.30 p.m.—Mr H. W. Vallender: "Whither Detergents?".

Monday, January 8-Tuesday, January 9

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP, and the PHYTOCHEMICAL SOCIETY (at the School of Pharmacy, Brunswick Square, London, WC1)—Symposium on "Plant Growth Regulators".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:
ASSISTANT (young graduate in chemistry or biochemistry, or a technician with appropriate experience) in the DEPARTMENT OF GENETICS to help with a project involving amino acid sequence determination in a protein)—Professor J. R. S. Fincham, The University, Leeds, 2, Yorkshire (January 5).
POSTDOCTORAL FELLOW OF POSTGRADUATE ASSISTANT (with a first-class or upper second-class honours degree or research experience in the field of electronmicroscopy or biochemistry) to study the mechanism of cold hardi-

ness in marine invertebrates—The Registrar, University College of North Wales, The Marine Science Laboratories, Menai Bridge, Anglesey (January 8).

CHAIR OF CANCER STUDIES and the DIRECTORSHIP OF THE LABORATORIES OF THE BRIMINGHAM BRANCH OF THE BRITISH EMPIRE CANCER CAMPAION—The Registrar (R.S.), University of Birmingham, P.O. Box 363, Birmingham, 15 (February 12).

PLANT BREEDER (with a good honours degree in plant science and postgraduate experience in plant breeding or genetics) for studies in vegetable breeding and their application to development of improved varieties—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (January 12).

RESEARCH ASSISTANT (honours graduate) in the Department of Physics to work on X-ray diffraction investigations of virus structure—Professor K. J. Standley, Department of Physics, The University, Dundee, Scotland (January 13).

LECTURER/ASSISTANT LECTURER (preferably with an honours degree, or equivalent, in science or agricultural science, and a higher degree in biochemistry, or an honours degree, or equivalent, in science or some similar combination of subjects) in Agricultural Biochemistry with a higher degree in agricultural science, nutrition, or plant science, or some similar combination of subjects) in Agricultural Biochemistry. University of Malaya—The Association of Commonwealth Universities (Branch Office).

Marlborough House, Pall Mall, London, SW1 (Kuala Lumpur and London, January 15).

LECTURER in both Theoretical and Experimental Physics—The Registrar, The University of Warwick, Coventry CV4 7AL (January 15).

SENIOR LECTURER (Diochemist) in the School of Mog.Ecular Sciences—The Registrar, University of Warwick, Coventry CV4 7AL (January 15).

SENIOR LECTURER in LECTURER (Inversity PLANT Physiology at the University

Registrar, The University of Warwick, Coventry CV4 7AL (January 15).

LECTURER or ASSISTANT LECTURER (bicchemist) in the SCHOOL OF MCLECULAR SCIENCES—The Registrar, University of Warwick, Coventry CV4 7AL (January 15).

SENIOR LECTURER or LECTURER IN PLANT PHYSIOLOGY at the University of the Witwatersrand, Johannesburg, South Africa—The Association of Commonwealth Universities (Branch Office), Mariborough House, Pall Mali, London, SW1 (South Africa and London, January 15).

LECTURER (medical candidate) in the DEPARTMENT OF BACTERIOLOGY—The Registrar, The University, Liverpool, 3, quoting Ref. RV/202/N (January 17).

PLANT PHYSIOLOGIST (with a Ph.D. degree or relevant postgraduate experience of equivalent standard and duration supported by satisfactory evidence of research ability) in the DIVISION OF PLANT INDUSTRY, Riverina Laboratory, Commonwealth Scientific and Industrial Research Organization. Deniliquin, NSW, Australia, to be responsible for initiating a research programme into one or more of the following physiological aspects of plant—water relations: (1) the ability of semi-arid and arid zone plant species to tolerate desiccation, (2) the fundamental relationships between water stress and growth of these species, (3) mechanisms for restriction of water loss.—Mr R. F. Turnbull, Chief Scientific Liaison Office, Astrica House, Kingsway, London, WC2, quoting Appointment No. 132/169 (January 18).

SENIOR LECTURER Or LECTURER in BIOCHEMISTRY at Victoria University of Wellington, New Zealand—The Association of Commonwealth Universities (Branch Office), Mariborough House, Pall Mall, London, SW1 (New Zealand and London, January 19).

CHAIR OF PHARMACOLOGY—The Secretary, The University, Aberdeen, Scotland (January 20).

SENIOR LECTURER/ASSISTANT LECTURER IN PURB MATHEMATICS at the University of Hong Rong—The Association of Commonwealth Universities (Branch Office), Mariborough House, Pall Mall, London, SW1 (Hong Kong and London, January 19).

PERSY CHAIR OF ZEOLOGY—The Registrar, The University, Scheller (Perbuary

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one or two copies of NATURE each week is:

*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire.....£14.0.0 each United States of America......(by air freight).....\$48 each Canada......(by air freight).....\$52 each Elsewhere overseas by surface mail......£14.0.0 each

(Charge for delivery by air mail on application) *Shorter periods pro rata. (Minimum three months.)

MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

12 MONTHS (52 issues and 4 indexes)

Number of	G.B. &	U.S.A,	Canada	Elsewhere
Copies	Eire		freight)	(surface mail)
3–5 6–11 12 or more	Each £13.10.0 £12.15.0 £12.0.0	Each \$46.50 \$44.50 \$42.50	Eech \$50.50 \$48.30 \$46.00	Each £13.10.0 £12.15.0 £12.0.0

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address. (ZIP essential for U.S.A.)

Selected Lectures of THE ROYAL SOCIETY

VOLUME 1 November 1967, viii+256 pp., 45s.

We are pleased to announce that the Council of The Royal Society has accepted the invitation of Academic Press to co-operate in producing this first volume of selected lectures which have been given before the Society by distinguished scientists during the last few years.

Though the lectures have already appeared in the Society's *Proceedings*, it was agreed that a far broader readership would be interested in obtaining a selection of carefully prepared lectures written by experts in their particular fields, on subjects covering a wide variety of recent scientific advances.

The Selected Lectures of The Royal Society will appear as an annual series and this first volume contains selections from the lectures given during the period 1963–1966. Subsequent volumes will contain major lectures selected from those given in the year immediately prior to publication.

Please write for fully descriptive leaflet

CONTENTS

F. Barth:

NUFFIELD: Anthropological models and social reality.

J. D. Bernal:

BAKERIAN: The structure of liquids.

Sir Lindor Brown:

CROONIAN: The release and fate of the transmitter liberated by adrenergic nerves.

M. Calvin:

BAKERIAN: Chemical evolution.

Henry Harris:

REVIEW: Hybrid cells from mouse and man: a study in genetic regulation.

W. Hayes:

LEEUWENHOEK: Some controversial aspects of bacterial sexuality.

P. Kapitza:

Recollections of Lord Rutherford.

M. V. Keldysh:

Organization of science in U.S.S.R.

R. R. Race:

REVIEW: Contributions of blood groups to human genetics.

W. A. H. Rushton:

FERRIER: Visual adaptation.

G. de Santillana:

WILKINS: Galileo today.

F. C. Williams:

BAKERIAN: Inventive technology; the search for better electric machines.

J. Z. Young: CROONIAN: The organization of a memory system.

APPOINTMENTS VACANT

AUSTRALIAN NATIONAL UNIVERSITY

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES

SCIENCES

Applications are invited from scientists interested in the principles of taxonomy and its application to the Australian flora. It is expected that two appointments may be made, one as Senior Fellow or Fellow, the other as Research Fellow. Those appointed would be expected to devote their whole time to the systematic revision of the flora, with a view to producing a definitive Flora. Co-operation with scientists in C.S.I.R.O. in Canberra will be encouraged. The salary of a Fellow is determined in the range \$A6.400 to \$A8,740 and of a Senior Fellow in the range \$A8.750 to \$A10,274. Appointment is made for an initial period of five years; thereafter he may be reappointed until retiring age. A'Fellow is entitled to one year's study leave on full pay, plus a contribution towards travel and other expenses, in every seven years; a Senior Fellow one year in every six years' service.

a Senior renow one year.

The salary of a Research Fellow is determined in the range \$A5,400 to \$A7,250. Appointment is usually for three years with a possible extension to five years.

Superannuation is on the F.S.S.U. pattern with supplementary benefits. Reasonable travel experience with housing is

plementary benefits. Reasonable travel ex-ses are paid and assistance with housing is

penses are paid and assistance with housing is provided.
Further particulars may be obtained from the Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1.
Applications close in Australia and London on Pebruary 29, 1968. (2140)

UNIVERSITY OF MALAYA FACULTY OF AGRICULTURE

FACULTY OF AGRICULTURE

Applications are invited for the post of Lecturer/Assistant Lecturer in AGRICULTURAL BIOCHEMISTRY. Applicants should have preferably an Honours degree (or the equivalent) in Science or Agricultural Science and a higher Degree in Blochemistry, or an Honours Degree (or the equivalent) in Blochemistry with a Higher Degree in Agricultural Science, Nutrition or Plant Science, or some similar combination of subjects. Duties consist mainly in teaching the one-year course in Agricultural Biochemistry towards the four-year B.Agr.Sc. Degree and supervision of research projects by graduate students. The one year course serves as a basis for subsequent Plant and Animal Nutrition and Physiology courses. Good labotatory facilities are available for research into biochemical aspects of plant, animal or food sciences.

Salary Scales: (appropriate sterling equiva-

animal or food sciences.

Salary Scales: (appropriate sterling equivalents), Lecturer, £1,498 by £65 to £1,889/£1,954 by £73 to £2,320 per annum; Assistant Lecturer, £1,303 by £65 to £1,433 per annum. In addition, the following allowances are payable:

Variable Allowance: 35 per cent of basic salary, subject to certain maxima depending on marital status; minimum £244 per annum; maximum £651 per annum.

Inducement Allowance: (if awarded), varies (a) for Lecturers, up to £488 per annum; (b) for Assistant Lecturers, up to £326 per annum.

Housing will be provided, if available, for which a rent of £163 to £204 per annum will be charged.

Provident Fund: Staff member contributes 5 per cent and University 15 per cent of basic salary.

Further particulars and application forms are

salary.

Further particulars and application forms are obtainable from the Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1. The closing date for the receipt of applications in Kuala Lumpur and London is January 15, 1968.

CSIRO

GEOCHEMIST OR GEOLOGIST **AUSTRALIA**

DIVISION OF APPLIED MINERALOGY

GENERAL The Division of Applied Mineralogy is a component of the Chemical Research Laboratories of the Commonwealth Scientific and Industrial Research Organization with its headquarters in Melbourne. A group comprising the Western Australian Laboratory of the Division is located in new air conditioned premises at Floreat Park, a suburb of Perth. The Laboratory's programmes are concerned with the elucidation of the chemistry and physics of geological processes, with the dual aims of providing new approaches to geochemical exploration and of devising new methods of treating economic minerals.

The Laboratory is equipped for hydrothermal and electro-chemical work, for chemical analysis, atomic absorption and X-ray fluorescent spectrometry, for optical mineralogy and mineragraphy, and for X-ray diffractometry and crystallography.

DUTIES A geochemist or geologist with a strong background in chemistry, and preferably with some experience of metallurgical procedures, is required to take part in the research programmes in one or more of the following fields: dispersion haloes around ore bodies; the effect of weathering and of laterization on economic minerals; experimental geochemistry applied to ore minerals, their formation, alteration and treatment.

QUALIFICATIONS Applicants should have a Ph.D. degree in Geology, Chemistry or Metallurgy, preferably with relevant postgraduate research experience, or have had postgraduate research experience of equivalent standard and duration supported by satisfactory evidence of research ability.

SALARY Depending upon qualifications and experience, the appointment will be made within the salary ranges of Research Scientist, \$A5,250-\$A6,622 p.a. or Senior Research Scientist, \$A5,250-\$A6,622 p.a. or Senior Research Scientist, \$A6,892-\$A7,974 p.a. In the case of an applicant having a background of extensive and appropriate research experience, appointment in the range of Principal Research Scientist, \$A8,242-\$A9,490 p.a. will be considered. Salary rates for women are \$A428 p.a. less than the corresponding rates for men. Promotion within SCIED to a higher description in determined by men and the promotion of the pro within CSIRO to a higher classification is determined by merit.

CONDITIONS Fares paid for the appointee and his dependent family. Further particulars supplied on application.

Applications (quoting Appointment No.: 604/52), and stating full name, place, date and year of birth, nationality, marital status, present employment, details of qualifications and experience, together with the names of not more than four persons acquainted with the applicant's academic and professional standing, should reach:

Mr R F Turnbull Chief Scientific Llaison Officer Australian Scientific Liaison Office,

Africa House, Kingsway, London, W.C.2, by the 31st January, 1968.

(2143)

WOLVERHAMPTON HOSPITAL MANAGEMENT COMMITTEE

MANAGEMENT COMMITTEE

BIOCHEMIST

Applications are invited for the post of Biochemist (Basic Grade) which fails vacant on February 1, 1968. Candidates should possess an Honours Degree in Chemistry or Biochemistry or equivalent qualifications. In addition to routine work opportunities exist for instruction in Background Pathology and for research. Candidates may visit the laboratory by arrangement with Dr. G. Walters at New Cross Hospital, Wolverhampton. hampton.

ampton.
Applications, with names of two referees, to general Royal Hospital, Wolver(2134)

CHARING CROSS HOSPITAL MEDICAL SCHOOL

Research Assistant required for work on cell culture using foetal and adult haemopoietic tissue. Tenable for one year in the first instance but subject to renewal. Salary on the range of £750 to £950.

Further particulars can be obtained from Dr. G. D. Pegrum, Department of Haematology, Charing Cross Hospital Medical School, 62-65 Chandos Place, London, W.C.2, to whom applications should be addressed in writing, giving details of experience and names of two referees. (2125)

LANCHESTER COLLEGE OF TECHNOLOGY COVENTRY

DIGITAL COMPUTER PROGRAMMER

Previous programming experience is essential for this post. Mathematics to degree level is desirable. Training in programming language for the Elliott 803B Computing System is available. Salary: £1,220 to £1,665 per annum; Commencing salary according to age, experience and qualifications. This is a permanent post with Coventry Corporation with superannuation, staff status, monthly salary, generous sick leave and holiday schemes. Refectory available.

Application forms obtainable from the Principal, Lanchester College of Technology, Priory Street. Coventry, returnable by January 11, 1968.

TECHNICIANS REQUIRED TWO TECHNICIANS REQUIRED IN Immunology Department: one for biochemical and immunochemical studies for which previous experience in protein or nucleic acid biochemistry, or radioactive work, an advantage; and one for work on cellular aspects of Immunology for which previous experience in tissue culture, microbiology or haematology an advantage. Salary within the scale £904 to £1,131.—Apply Secretary, St. Mary's Hospital Medical School, London, W.2. (2112)
